How could I faintly bend the knee,

And turn idolater to thee!

'Tis Nature's worship—felt—confessed,

Far as the life which warms the breast."

* * * * *

The new-born infant stands in need of heat, and especially of vital heat, as that of the mother, or a sort of incubation. Instinct directs quadrupeds, to afford the breast and place the young between the legs, while birds cover their young with their wings. Reptiles too expose their young to the heat of the sun. All quadrupeds and birds prepare a warm bed or nest for their young, and the new-born infant should have the same care, and be properly clothed so as to protect it from the cold. It is therefore contrary to nature to expose it to cold as recommended by some writers, and practised by some nations as already mentioned.

Though an infant should be placed in bed with its mother immediately after birth, and allowed to repose in this situation for a few

days, some say nine days, yet the practice cannot be long continued, as too much heat is imparted by the mother, the new being rendered liable to the impression of cold, and the parent, whose chest must be uncovered, suffers from the last inconvenience. The air of the bed impregnated with the changes which take place in the respiration of the mother, is unfit for the well-being of the infant, but of this I shall speak more fully hereafter. I shall now briefly notice the management of new-born infants, and dilate upon the precepts herein inculcated as I proceed.

Hygiene of Infancy.—This expression is applied to the collection of precepts which are to be followed to procure infants a sound and vigorous constitution. These are based upon nature, science, and experience, but are modified by climate, condition, sex, and a thousand other circumstances. Nevertheless we may lay down general rules, but these are liable to exceptions.

Infantile hygiene was enriched by the writings of many physicians, as I stated in my first lecture, but more especially by Andry, Buchan, Ballexserd, Dessessart, Virey, &c.; while the moral education of infants was vastly improved by illustrious philosophers, Locke, Montaigne, Fénelon, Rousseau, and many others.

In treating of the physical and moral education of infants, we must follow nature and the established principles of our science. These guides will enable us to detect and refute a host of errors and prejudices.

It is lamentable to reflect on the universal ignorance of all classes of society, except our own profession, on the management of infants and children. Persons often take great interest in rearing domestic animals, but if we speak to a father on the physical education of his infant he almost feels offended; but ask him about his dogs and horses, and he is ready to give his views on rearing them.

It would be extremely beneficial to the interests of humanity were there some popular work on the hygiene of infancy; and it is somewhat surprising that amidst the incessant publication of all kinds of useful and instructive works, there is not one on this important subject. But we view the infant from the moment of birth, and observe its delicacy and feebleness, without reason or experience to guide it or enable it to appreciate what is beneficial or injurious to its existence. The delicacy and excitability of its brain, nervous system, skin, digestive system, eye, ear, taste, &c., render it liable to be affected by all surrounding bodies, and to an immense number of disorders and diseases from the slightest causes. The anatomical, physiological, and pathological conditions peculiar to it, will form matter for consideration at a future time; and slight allusion to them at present is necessary to remind us of the rules and cautions to be observed for the conservation and development of the infant.

As soon as it is cleaned and dressed it is placed with its mother, or in a cot or cradle by itself. It ought to respire a pure air, not too cold or too hot, too dry or too moist, and it should not be exposed to the vicissitudes or changes of the weather. An impure, fetid, or bad air, is not calculated for its respiration, and hence death destroys an immense number of infants in hospitals and in the unhealthy abodes of the poor. For the same reason infants that sleep with their parents are too warm, deprived of good air, and become weak or sickly.

The first care it requires is nourishment, and this is supplied by the mother's milk, which possesses an aperient property, and evacuates the contents of the bowels. But nurses generally administer some medicine for this purpose, which is totally unnecessary when the mother has breast milk. The infant has had no evacuation from the bowels during its sojourn for nine months in the womb. Birth is the period of all kinds of evacuation, and particularly of the contents of the intestines called *meconium*. The changes that take place in the economy of the infant at birth, the irritation of the air on the skin and lungs, the efforts of crying or breathing often expel the contents of the intestines and bladder, in many cases before the infant is washed and dressed. If this evacuation does not happen, the first food, whether breast milk or other aliment, usually effects it. The application of the infant to the breast is important to the mother as well as to itself, because it instinctively sucks, and thereby prevents painful swelling of the breast, milk fever, and sore nipples. The first milk, called *colostrum*, is serous and purgative; it titillates the infant's bowels, excites their action, and evacuates the meconium. When the milk is not formed at birth, nurses administer sugar and water, sugar and butter, syrup of violets, almond or castor oil to open the bowels. In France they use syrup of chicory, composed of one part of syrup of rhubarb and three of water, or a drachm of manna dissolved in water.

A mild aperient is necessary, when a wet nurse, whose milk has been secreted for several weeks before the birth of her foster-child is employed. It is of great importance to cause the evacuation of the meconium in negro children, as it is supposed to excite fatal convulsions. We often observe the retention of the meconium in our infants excites jaundice, screaming, want of sleep, griping, and sometimes convulsions. When the infantile bowels are regular every day, it is quiet, sleeps, takes its food, and thrives very rapidly. The natural colour of the alvine motions is a light yellow, any other is a proof of disease.

It is essentially important to health that the nurse should keep the infant neatly dressed and perfectly clean, and that she change its dress whenever it is wetted or soiled, and that she wash its thighs with warm water whenever they are soiled to prevent chafing or exco-

riation, and afterwards powder them. The clothes should be suited to the season, and should be worn very loosely so as to allow a free motion of the trunk and extremities. The clothing next the skin should be soft and warm.

The cradle or bed should be furnished with a mattress of hair, of oaten straw, or fern; feathers, down, and wool, should be forbidden, because the heat renders the infant uncomfortable, and the softness induces bad attitudes of the body. The bed should be hard, the clothes soft and warm. All savage and domestic animals and the weakest birds make hard beds for their young, and cover them warmly. This method is essential to give perfection to the strength of man. A soft bed weakens a child, and a hard one strengthens it. On the former the muscles have a vacillating support, like a soft soil on which a person walks with difficulty and fatigue, because the effort is continual, and because there is no fixed point for support. The infant perspires too much in a soft bed; it becomes relaxed, and its urine and excrements readily escape from it. On a hard bed all the body is fortified, and the infant walks much sooner. Lyncurgus ordered the cradle to contain beaten reeds, with a warm covering. Plutarch attributed the strength and graces of Alcibiades to the Spartan methods by which he was reared; and Greeks and Romans employed Spartan nurses for their children. Hard beds are the most proper for ensuring muscular energy. The infant seldom soils itself in them, more especially if, when taken up, gentle friction is applied over its abdomen and loins, which will induce the evacuation of the bladder and bowels. When this friction is practised at regular hours the infant learns a habit of cleanliness. It should be placed on the right side in bed with the mother, with the head and shoulders slightly raised, as this position facilitates the rejection of the saliva or mucus, when the infant has catarrh or cold; and also the passage of the food through the stomach, which is from the left to the right side. It may be placed on the left side alternately with the right, but the latter is preferable after the ingestion of aliment. The cradle or cot should be covered to moderate the impressions of light and cold, but there ought to be a sufficient aperture for the free admission and renewal of air. Pure air is essential to respiration, and aliment to the growth of the body, and this is supplied by the mother's milk.

GENERAL DISPENSARY, ALDERSGATE-STREET.

ON Saturday night last a meeting of the members of the Westminster Medical Society took place in the Hunterian Museum, Great Windmill-street, pursuant to a notice, that "the sense of the Society be taken on the subject of

the resignation of the physicians and surgeons of the General Dispensary, Aldersgate-street, with the view of giving the thanks of the Society to those gentlemen for their conduct, and of expressing at the same time the feeling of the Society relative to what virtually amounts to the sale of professional appointments."

Mr. Pettigrew took the chair in virtue of his office of President.

Dr. Gregory, in commencing the discussion, said he thought he need offer no apology for bringing under the notice of the Society a subject deeply affecting the character and dignity of the medical profession. They had lately witnessed an extraordinary event: six medical gentlemen, of great reputation and scientific attainments, had simultaneously resigned situations in the General Dispensary; and the conduct of those gentlemen could not be a matter of indifference to any body of their professional brethren. (*Hear, hear.*) They must either have acted wrongly or rightly. (*Hear, hear.*) He had not thought proper to attend the meeting which took place at the Freemasons' Tavern relative to this subject, because he understood that it was convened to support the medical officers, and he did not approve of their conduct in every particular. For instance, he did not admire the sarcastic quotation of which one of them made use of from Cato, nor could he take their part in a trifling and paltry dispute about a side entrance to the Aldersgate-street Dispensary. He thought they were also to blame for having resigned their situations in a hurry, without giving the Governors an opportunity of filling up the appointments. But

—"Non ego paucis
Offendar maculis;

and he was therefore prepared to support them on the important principles, that the interests of the sick poor, and the respectability of the medical profession, required that medical appointments in public dispensaries should be free even from the suspicion of purchase. (*Hear, hear.*) This opinion was confirmed by the custom now established with regard to surgeonships and assistant-surgeonships in the army. There was a time when these places might be bought and sold, but the practice was put a stop to, because it was found to be derogatory to professional character, and detrimental to the efficiency of the service. (*Hear, hear.*) In the East India Company's service any man attempting to sell an appointment of this nature was liable to be indicted, while the party proposing to purchase it was declared incapable of serving his Majesty. (*Hear, hear.*) He also begged to call the attention of the meeting to the course pursued by the House of Commons with respect to the Irish infirmaries. They refused to vote one shilling of the public money to those institutions, unless a regulation was established preventing subscribers of less standing than twelve months from voting at elections for officers. (*Applause.*) In London charitable institutions were gene-

rally conducted on the principle, that professional appointments should not be open to purchase, but the Governors of the Aldersgate-street Dispensary had thought proper to follow a different rule, and they defended their conduct, he believed, on the ground, that good medical officers were not wanting to those few institutions whose regulations were the same as those which they had just adopted. This was precisely a repetition of the argument so commonly used in defence of the rotten borough system—"it worked well;" but the people of England would not be satisfied with a bad principle because it worked well. (*Applause.*) The Governors of the Aldersgate-street institution had, in point of fact, converted their dispensary into a species of rotten borough, and, until their late resolution was rescinded, he hoped it would be spoken of as the Old Sarum of medical charities. (*Applause and laughter.*) He concluded by moving a resolution, declaring that the interests of the poor and the respectability of the medical profession required that the appointments to public charities should be free even from the suspicion of being open to purchase.

Mr. Griffiths stated that he concurred in every word that had fallen from Dr. Gregory, and felt pleasure in seconding the resolution.

Carried unanimously.

Mr. Chinnock, in moving a resolution declaring that the regulation lately adopted by the governors of the Aldersgate-street Dispensary, in permitting persons to vote who became governors seven days previous to the election, amounted virtually to the sale of professional appointments, observed that the effect of the regulation would be to open the doors of charitable institutions to inexperienced youths with plenty of money in their pockets, instead of to persons of mature talents. He himself knew a gentleman who would have been very glad to expend five hundred guineas to place his nephew, who had just obtained his certificate, in a public dispensary. If the members of the medical profession would only unite firmly together, and display an *esprit de corps*, they might easily prevent the execution of such an obnoxious regulation as that to which the resolution alluded. (*Hear.*)

Dr. Ryan seconded the resolution. He condemned the regulation adopted by the governors of the Aldersgate-street Dispensary, as tending to the introduction of inexperienced persons to situations which none but men of ability and practice ought to fill. He gave the governors credit for having put down premature canvassing and proxy votes; but they destroyed these salutary changes by allowing persons to make votes a few days before the election. In fact, they allowed a physician or surgeon of a day's standing to compete with practitioners of eminence and experience. Their law deprived the poor of the best advice, to which they are entitled on the grounds of humanity.

Carried unanimously.

Dr. Webster said that, believing the conduct

of the late medical officers of the Aldersgate-street Dispensary to be highly deserving of approbation, he felt great pleasure in proposing a resolution of thanks to those gentlemen. (*Hear, hear.*) It had been said that they ought not to have exposed the sick poor to danger by a precipitate retirement. From that opinion he totally dissented, and he thought no imputation could be cast upon their character in consequence of their resignation. Upon retiring they had declared that they would willingly attend to the sick poor of the dispensary until their places were supplied by others; and it would be in the recollection of the meeting that an advertisement very soon afterwards appeared in the newspapers, notifying that a physician and surgeon were, as usual, in constant attendance at the Aldersgate-street institution. No injury to the sick poor had, therefore, resulted from the retirement of the late medical officers. (*Hear.*) After passing a high eulogium on the character and abilities of Dr. Birkbeck, and the other medical officers of the Aldersgate-street Dispensary, Dr. Webster concluded by proposing that the cordial thanks of the Society be given to those gentlemen. (*Applause.*)

Mr. Millington seconded the resolution.

Dr. Epps rose and said, Sir, I oppose this resolution; I approve entirely of the principle, that no public Institution should be open to purchase, and I have voted for the resolution moved by Dr. Gregory: to this, indeed, I cannot consent, and must beg that, as we are met to inquire respecting the resignation of the medical officers, the Society, from whom I perceive I differ from the manifestations of applause, will hear the grounds on which I must vote in opposition to this resolution. I find, Sir, that the Aldersgate-street Dispensary was established in 1770, and that one of the laws thereof, till the year 1825, was, that any person might vote who subscribed four days previous to the election, *proxy* and *personal* votes being admitted. It is well known also, that this law was altered in 1825, and the regulation was introduced, that no person (excepting Life-Governors) should vote unless he had been a Governor of six months' standing. The Committee, it is also well known, perceived, as they imagined, the injurious effect of this law, and succeeded in reverting, not to the original law, but to one which virtually abolished proxy voters, so far as they might act injuriously in an election, and gave to Governors of seven days' standing the power of voting in person. This law the Committee further protected by passing a very salutary regulation:—"Every person to be incompetent to be a candidate, who, either directly or indirectly, shall solicit, or authorise, or permit any person to solicit the vote of any Governor in his favour previously to the notification of the vacancy by public advertisement." I ask, Sir, what regulation can be more excellent, more tending to promote the dignity of our profession? In addi-

tion to this, they passed another regulation, "That no person shall be eligible as a candidate for any medical office whose testimonials shall not have been previously approved of by the Medical Committee." The liberal constitution of this Committee I admire (*here Dr. Epps was called to order*). I referred, Sir, to the Committee, because I might show that they had not acted so injuriously to the dignity of the profession as had been implied; and also that, as the approbation of the conduct of the medical officers will, by implication, condemn the alleged misconduct of the Governors, I thought it but fair to notice the real condition of things in reference to this much-spoken-of resolution. It is well known, that in consequence of this new regulation having been passed, the medical officers resigned: and the resolution before us gives the cordial thanks of this Society to these medical officers for so doing. I would have given my cordial thanks to these gentlemen if they had acted consistently throughout; but when I look to the names of these gentlemen and find that Dr. Birkbeck, Dr. Clutterbuck, and Dr. Lambe came into the Charity under the *old* regulation (not guarded like the present one) namely, Drs. Birkbeck and Clutterbuck in 1807, and Dr. Lambe in 1812, what am I to think of these advocates, in 1833, of the dignity of the profession; for surely if these gentlemen joined an institution having this denounced law, surely the dignity of the profession was as much offended *then* as *now*. I do not say that Dr. Birkbeck, Dr. Clutterbuck, or Dr. Lambe made use of this law to get themselves into the Charity; no, for there was no contest in the case of these three gentlemen; but my wonder is, that they should have identified themselves with, and sought admission into, a Charity having a law, from which Charity they now make it a virtue to depart, on the ground, that a law, in their minds, similar to that under which they joined the Charity has been enacted. Surely, if it be honourable in them to resign now, what must be the conclusion regarding their having sought admission then? There is a want of consistency; and, as exhibiting this want of consistency, I cannot give them my cordial thanks. (*Hear*.) Another gentleman, whose name I find among those who resigned, is Mr. Salmon. Now I find that Mr. Salmon tried to obtain admission into the Aldersgate-street Dispensary in the year 1820, and he had 127 votes. This same gentleman, or, at least, a gentleman of the same name, stood again, in 1825, in opposition to Mr. Ellerby, and had 636 votes, while Mr. Ellerby had 643. Now, are we to imagine that the public estimation in which this gentleman was held by the Governors of the charity could occasion this augmentation in votes from 127 to 636 in the course of four years? This might be; but such a favourable inference is completely overturned by the fact, that at the next election, at which Mr. Salmon gained the object of his ambition,

he had only 315 votes. Now where were all the Governors who voted for Mr. Salmon on the preceding occasion: more than 300 of his supporters in 1824 were absent on this, a contested election. Now what must I infer from this, namely, that the report which prevails is true,—that Mr. Salmon made voters on the occasion. Now, Sir, I ask you, and the members of this Society how can a person, who made use of this system of making money voters, claim merit to himself in resigning, because a law, somewhat similar, although materially different in some respects, is re-enacted? (*Here again called to order*.) In conclusion, Sir, I beg to state that, under these grounds, namely, that three of the medical officers, namely, Dr. Birkbeck, Dr. Clutterbuck, and Dr. Lambe, came into the charity with the regulation, which they now condemn, staring them in the face; and further, that a fourth, Mr. Salmon, had made use of the very law which he now so deprecates, I cannot but oppose the giving to *them* the cordial thanks of the Society*.

Mr. Pettigrew requested Dr. Epps to confine himself more strictly to the question under discussion.

Dr. Epps said that his object was to show that the committee of the Aldersgate-street Dispensary were not so much to blame as some persons would have it believed. One of the resolutions which they passed—that no candidate should directly or indirectly canvass for a place until its vacancy was publicly advertised—reflected the highest honour on them. They also adopted a regulation abolishing the evil of proxy votes, and resolved that no person should be eligible as a candidate whose testimonials were not approved of by the medical committee, which was composed of gentlemen belonging to every branch of the medical profession. (*Question, question, and disapprobation*.) He was unwilling to weary the meeting, and he would at once withdraw his opposition to the motion, if Mr. Salmon would declare that he had not expended two hundred guineas in the purchase of votes at the Aldersgate-street Dispensary. (*Disapprobation and general cries of No.*)

Mr. Salmon, who was present as a visiter, said that when the proper time arrived he should be able to vindicate his own character and to place Dr. Epps in that position in which he ought to stand. (*Hear, hear.*)

Dr. Epps said that the impression on his mind was, that Mr. Salmon had, for electioneering purposes, created a vast number of governors. (*Question.*)

Dr. Johnson rose to order. The resolution before the society referred to a specific part of the conduct of the medical officers of the Aldersgate-street Dispensary, and it was con-

* We have considered it an act of justice to Dr. Epps to give a full report of his observations, as they were so strongly opposed to those of the other members of the Society.

suming time to no purpose to rake up the history of past transactions. (*Hear, hear.*)

Mr. King hoped that the resolution would pass unanimously, but in order to obtain that desirable result, he thought it was necessary to discuss the question fully in all its bearings.

Mr. Pettigrew thought that Dr. Epps was travelling too far wide of the motion; the time of the meeting was limited, and it was therefore desirable to keep as strictly as possible to the question under discussion.

Dr. Epps said that he considered the conduct of the Governors of the Aldersgate-street Dispensary would be impliedly censured by passing a vote of thanks on the late medical officers; and he had therefore thought proper to state what the governors had done. There was but one more point to which he would call the attention of the meeting before he sat down. The late regulation of the dispensary prevented governors of less standing than six months from voting, governors for life excepted. This was a most important exception, as it allowed the manufacture of any number of votes, on the payment of ten guineas for each, and yet this was the regulation of which the late medical officers of the dispensary, who pretended to be such sticklers for the dignity of the profession, approved.

Dr. Sigmond could have hoped that no person would have been found to oppose a resolution which had met with the unanimous approbation of every class of the profession. In his opinion the late medical officers of the Aldersgate-street Dispensary had conducted themselves most properly under circumstances of peculiar difficulty. (*Hear, hear.*) He did not think that they were bound to support an obnoxious law because it was in existence when they joined the dispensary; on the contrary, the very circumstance of having felt the inconveniences arising from the law would naturally induce them to oppose it. (*Hear, hear.*) Sir F. Burdett, who had been a reformer all his life, entered the House of Commons by means of the close borough of Boroughbridge, but he did not, therefore, consider himself precluded from exposing the evils of the borough system. In his opinion the society ought to feel deeply indebted to the gentlemen who had been the first to make a stand for the honour of the profession; and he had no doubt they would receive the thanks of the whole meeting, excepting Dr. Epps. (*Applause.*)

Mr. King was ready to give his thanks to the late medical officers of the Aldersgate-street Dispensary; but at the same time he thought that no censure should be cast on the Governors of the institution. He was convinced that their conduct was not actuated by any feeling of hostility towards their medical officers. The mischief was in the system, and not in the men.

The resolution was then put and carried, Dr. Epps being the only person who opposed it.

Dr. Copland moved a resolution of thanks

VOL. IV.

to his Royal Highness the Duke of Sussex, for having marked, by resigning the office of President of the Aldersgate-street Dispensary, his disapproval of the regulation lately adopted by the Governors.

The resolution having been seconded, was carried unanimously.

The next resolution, proposed by Dr. Somerville, declaring "that any physician or surgeon who avails himself of the regulation lately adopted at the Aldersgate-street Dispensary, and thus virtually purchases a medical appointment, will thereby forfeit the respect of his professional brethren," was also carried unanimously.

Dr. Birkbeck then presented himself to the notice of the meeting amidst great applause. He said it was impossible for him to be indifferent to the opinions of the body he had the honour to address; but highly as he valued their vote of thanks, he regarded it as insignificant when compared with the resolution which preceded it, and which established the principle for which he and his colleagues had contended. (*Applause.*) If he had thought that the observations directed against the late medical officers of the Aldersgate-street institution could have influenced the decision of that meeting, he should have risen earlier, to state facts which as yet had not been stated, for the purpose of preventing an erroneous impression being produced; but he felt it was impossible for that society not to perceive to what sources the individual from whom those observations proceeded had applied for the facts, as he called the statements which he had made. That individual had, indeed, taken especial care not to make acquaintance with these whose communications might have led to the material modification, if not the entire suppression, of his speech. (*Great applause.*) It had been imputed to himself and his late colleagues that they obtained their appointments in the Aldersgate-street Dispensary by the assistance of a law which they now condemned. In reply he begged to state that they had derived no assistance from that law; and when he was told that he might obtain the situation of physician to the dispensary, to the exclusion of Dr. Clutterbuck, by making governors, he at once said that if such means existed, they should not be employed by him. (*Hear, hear.*) He also knew that Drs. Clutterbuck, Lamb, and Lloyd, and Mr. Pereira, refused to avail themselves of that obnoxious regulation, and Dr. Epps, if he had taken the trouble to inquire why so few governors were present at some of the elections, might have learned that the reason was because there was no opposition. (*Hear, hear.*) As soon as Dr. Clutterbuck and himself possessed the power, they proposed the adoption of a new regulation, the necessity of which was made more apparent by the unfortunate scenes of riot and uproar created by guinea and pocket voters, which followed the election in which Mr. Salmon was engaged—honourably he

F F

(Dr. Birkbeck) would undertake to say, notwithstanding all the insinuations to the contrary. (*Hear, hear.*) The regulation, as originally proposed, provided that no governor of less standing than twelve months should have a vote; but the opposition to this proposition was so great that they were glad to compound for six months. They had also left out of the regulation those words which gave to life-governors the right of voting immediately on the payment of their ten guineas; but this was considered such an outrageous attempt to be virtuous as could not be endured, and they were obliged, for fear of losing the benefit of the rest of the regulation, to allow the ten guinea voters to remain. That was not their fault, but their misfortune. (*Hear, hear.*) However, the regulation was thought too good to continue, and accordingly attempts were made, from time to time, to alter it, which at last succeeded. It was then that he and his colleagues resigned, in order to show that they were resolutely determined to maintain the principle on which the regulation was founded; and if the course which they had pursued tended to the introduction of a sounder system, in reference to the appointment of medical officers to public charities, their purpose would be fully answered. (*Hear, hear.*) He begged, before he sat down, to return his thanks for the kind manner in which the meeting had been pleased to notice their conduct. (*Great applause.*)

Dr. Roberts begged to thank the meeting for the vote of approbation which they had passed on his conduct. In looking back at what he had done, he felt that he had nothing to apologise for, except, perhaps, an indiscreet quotation. (*Laughter.*) There was not a step taken by himself and colleagues with reference to the Aldersgate-street dispensary but he gloried in. (*Applause.*)

Mr. Salmon said that having been personally attacked in the course of that evening by a gentleman to whom, he was happy to say, he was an entire stranger, he thought it right to state what was the course he pursued in order to obtain the situation he lately filled in the Aldersgate-street Dispensary. He had been engaged in three contests, and during two of them he had never resorted to any other means of obtaining votes than canvassing the Governors whom he found in existence. That was well-known to the gentlemen who happened to be his opponents on those occasions. He had also determined to act upon the same principle in the third contest, when he heard that his opponent intended to buy the place by creating Governors. He then declared that he was willing and anxious to carry on the election in a fair manner, but that he would not submit to be beaten by a creation of new Governors; and he fairly told his opponent that if any attempt was made to defeat him by creating guinea-voters, he would use the same means in self-defence. (*Hear, hear.*) He was now opposed to every regulation by which

medical appointments of this nature were made purchasable; and he had often said, that if they were to be sold at all, the best plan would be to take them to Garraway's coffee-house, and dispose of them by public auction. (*Hear, hear.*) After this explanation, he trusted that Dr. Epps would admit that he had been deceived. In conclusion, he had only to observe that he highly appreciated the manner in which his conduct, dictated solely by a sense of what was due to the dignity of the profession and the interests of the public, had been taken notice of by the Society. (*General applause.*)

Dr. Epps said that the statement just made by Mr. Salmon confirmed what he said, that Governors were made by that gentleman for electioneering purposes. Still he was willing to admit that Mr. Salmon had explained the matter in a way that proved he had not been actuated by improper motives.

A resolution pledging the Society to bring the subject under the consideration of Parliament, and another thanking the medical gentlemen of Leeds and Nottingham for the part they had taken in reference to this matter, were proposed and carried unanimously.

Mr. Pettigrew, before leaving the chair, observed that he had hitherto abstained from expressing any opinion on the subject which had just been discussed, in consequence of its having fallen to his lot to discharge the duty of president; but as the meeting was now at an end, he had no hesitation in saying that he entirely concurred in the resolutions which had been passed, and should feel no hesitation in attaching his name to them.

The meeting then separated.

At the conclusion of the above discussion the following resolutions were unanimously agreed upon and carried.

It was moved by Dr. Gregory and seconded by Mr. Griffith, and resolved unanimously,

That in the opinion of this Society the interests of the sick poor, and the respectability of the Medical Profession, equally require that the appointments to public charities should be free from even the suspicion of being open to purchase.

Moved by Mr. Chinnock and seconded by Dr. Ryan, and resolved unanimously,

That in the opinion of this Society the Regulation lately adopted by the Governors of the General Dispensary, Aldersgate-street, permitting any person to attend and vote personally, who should become a Governor seven days prior to the election, amounts virtually to the sale of the professional appointment.

Moved by Dr. Webster, seconded by Mr. Millington, and resolved unanimously, with the exception of Dr. Epps,

That the cordial thanks of the Westminster Medical Society are due and are hereby given to Drs. Birkbeck, Clutterbuck, Lambe, and Roberts; also to Messrs.

Salmon and Coulson, for their noble and disinterested conduct in resigning their office, rather than tacitly assent to the introduction of a law which compromises the honour and independence of the Medical Profession.

Moved by Dr. Copland, seconded by Dr. Sigmond, and resolved unanimously,

That the most respectful thanks of this Society be tendered to His Royal Highness the Duke of Sussex for his liberal and enlightened conduct in retiring from the Presidency of the General Dispensary, Aldersgate-street, thereby marking the sense His Royal Highness entertains of the conduct of the medical officers in resisting the adoption of a most pernicious and obnoxious regulation.

Moved by Dr. Somerville, seconded by Mr. Hunt, and resolved unanimously,

That in the opinion of this Society any physician or surgeon who shall avail himself of such a law, and thus virtually purchase a professional appointment in any public charity, forfeits thereby his claim to the respect of his professional brethren.

Moved by Dr. Somerville, seconded by Dr. Sigmond, and resolved unanimously,

That the Society pledges itself to bring this, amongst other grievances, before such Committee as may be appointed by the House of Commons, to inquire into the practice and regulations of the medical profession.

Moved by Dr. Jewel, seconded by Dr. J. Wyatt Crane, and resolved unanimously,

That the thanks of this Society are justly due and hereby given to the Medical Practitioners of Sheffield, Nottingham, Cork, and other provincial towns, for their readiness to stand forward in support of the dignity of the Medical Profession.

Moved by Mr. Stodart, seconded by Mr. Greenwood, and resolved unanimously,

That these Resolutions be signed by the Chairman in behalf of the Society, and that they be inserted in the several Medical Journals and the following daily Papers, namely the *Times*, *Herald*, *Chronicle*, *Globe*, and *Standard*.

T. J. PETTIGREW,
Chairman.

EDWARD STODART, Sec.

OBSERVATIONS ON THE CHARACTER AND TREATMENT OF IRITIS.

BY CHARLES WARBURTON RIGGS, ESQ.
SURGEON.

(Concluded from page 302.)

ON inspecting the *iris*, its colour, if inflamed, will be altered; this discolouration will depend on the natural

colour and the degree and duration of the inflammation. As the change is produced by deposition of fibrine, an admixture of yellow with its colour, in health, may be anticipated, with a tinge of red. If the colour approach to that of green it will become lighter, mingled with yellow; if blue, it assumes a greenish hue; if dark, it will exhibit a reddish tint. In cases where the inflammation is high, globules of lymph will be deposited, of a yellow or amber colour, usually three or four in number, and occupying in general the papillary margin; they may, however, form in the ciliary border, or on the surface. There is sometimes seen, likewise, a detached substance in the lower part of the anterior chamber, of different magnitudes, varying in bulk from a pin's head to that of a small pea, called *hypopion*. The earliest deviation in the motion of the iris is that of sluggishness, unaccompanied by irregularity. This diminution in the brisk action of the iris may be partly owing to the injected condition of the part. Mr. Guthrie ascribes this to a state of turgescence of its vessels; he conceives that the mobility of the iris may be impaired, and contraction rendered irregular from a loaded state of the vessels, before any change in the organisation has occurred. Subsequently it becomes irregular, contracts imperfectly, or not at all; the papillary margin becomes thickened, irregular, contracted, and drawn backwards. A times the aperture of the pupil is dilated, at others contracted; it is in the generality of instances diminished. The pupil may be divided by a band of lymph, a net-work may obstruct the opening, or a complete closure of the pupil may happen. Under any of these conditions, especially the latter, restoration of vision by medical treatment is very ambiguous, and the prognosis ought consequently to be guarded.

An interesting question has arisen as to the origin of this affection—whether the disease ever exists in a sound state of the system, or is

idiopathic, or follows or arises from a general morbid state of the body, *specific* or *constitutional*. I cannot assent to the opinion, notwithstanding the high authority Mr. Lawrence's name attaches to it, that iritis is never simple or idiopathic. It is seldom so; but the weight of medical testimony is in favour of the possibility of the existence of the uncomplicated form of the complaint. In the summer of last year a case corroborative of the correctness of this opinion came under my observation.

A countryman, æt. 24, of a very robust frame, was attacked, after several hours' exposure to wet, while his face was exposed to a penetrating wind, by inflammation of the iris, ushered in by the usual symptoms, and uncomplicated by inflammatory action in any other texture. It showed the characteristic marks of iritis in the most indisputable manner; and although measures were promptly and vigorously used, it ended in adhesion, and slight permanent alteration of colour. This young man had not, I can attest, been the subject of syphilis or rheumatism, nor had he any symptoms of strumous diathesis.

That syphilis, rheumatism, gout, scrofula, and mercurialism, predispose in a peculiar degree, and in frequency in the order of their enumeration, to the affection, must, I think, be admitted. It is a sequence of fever among the poor in Dublin. It may occur from punctured wounds, or after extraction of cataract. The disease is, however, induced by secondary syphilitic action generally, and often co-exists with the syphilitic papular eruption, or the scaly eruption, sore throat, superficial ulcerations on the soft palate of a venereal nature, in cases where mercury was administered ineffectually, or acted deleteriously during its exhibition. Mercury may be the sole exciting cause, in particular where the body has been under the severer influence of the mineral frequently. I have known it attributed to the use of the warm bath during mercurialisation.

The first step in the treatment of this disease is the free abstraction of blood, if the inflammation be acute, and the strength of the patient do not contra-indicate its adoption. The intention should be that of producing a decided impression on the constitution; and the quantity of blood drawn must be proportionate to the accomplishment of this design. Without this preparatory step any course of treatment will be uncertain and injudicious. It lessens the local action, mitigates the general disturbance, and facilitates the curative operation of mercury. An acute attack may destroy vision in four or five days. The use of mercury is to follow immediately the abstraction of blood; it checks the action in the minute vessels, and prevents the inflammation from ending in adhesion.

Calomel and opium are in general use. The calomel and opium are to be given every third, fourth, and fifth hour; the calomel in doses of from three to five grains, until its constitutional influence is unequivocal. As soon as that is established, the pain and intolerance of light abate, the redness disappears, the motion of the *iris* is restored, the absorption of lymph is set up, the clearness of the *cornea* is restored in cases in which it had participated, and the aqueous humour becomes transparent. Whilst these effects are being brought on, the extract of belladonna is to be smeared over the superciliary region, and round the orbit night and morning. Many other substances answer this end. Henbane is used by some; but the belladonna, either in form of extract round the eye, or in solution to the globe, has superseded every other. It dilates the pupil, and prevents the adhesion of the *iris* to the crystalline capsule; or, if adhesions have formed they are elongated. It is supposed also to alleviate the pain, and with this view has been combined with opium; but this benefit is by no means certain. Topical applications are unavailing; local depletion by leeches or cupping may be highly

advantageous in the course of the treatment. This treatment is applicable to an acute attack.

In the sub-acute cases there is not the imperative call for the full effect of bleeding, nor the very rapid introduction of mercury into the system. Leeching or cupping may be substituted for the general bleeding if debility is apprehended, and the calomel apportioned in smaller doses, and given at longer intervals. In the chronic form of the complaint, a month or six weeks is not an unusual period for its duration; when it assumes this moderate and protracted form of action, there is consequently less necessity for the adoption of the vigorous and prompt measures already specified. These, however, are to be followed at the discretion of the practitioner, and may be relied on as bringing about a favourable issue.

Cases occasionally occur in which this treatment would be injudicious, or even hazardous. They are rare, but too frequent to be overlooked. There are individuals who cannot bear mercury in any quantity or form. Where this idiosyncrasy is known or found to exist, mercury must not be given, or its use must be discontinued on the manifestation of any untoward symptoms. The *mercurial rash* may be excited by a few grains of the mineral.

Iritis now and then comes on in conjunction with *syphilis*, when mercury would, if given in efficient doses, be unsafe. The sort of cases to which I allude will be met in the persons of young men of dissipated habits and broken up constitutions, with a tendency to tubercular deposition in the lungs, or strong evidence of its having already taken place. If mercury be given to check the *iritis*, it will be at the risk of exciting a fatal action in the chest. In those cases where it is accompanied by syphilitic eruptions, the blotches may degenerate into scabs, a phagedenic ulceration may ensue. The spirit of turpentine, as recommended by Mr. Carmichael, I have seen used in cases, such as I

have described, with entire success. Given to the extent of one or two drachms three times daily, I have witnessed a perfect cure. An alleviation was generally experienced on the third day of its use; and at the end of from twelve to sixteen days all traces of the disease had vanished.

The spirits of turpentine will be found a valuable subsidiary remedy in cases at least in which mercury is prohibited.—*Edinb. Med. and Surg. Jour.*

NORTHAMPTON INFIRMARY.— LITHOTRITY.

A NUMEROUS meeting of the medical gentlemen of this and the neighbouring towns took place at our Infirmary a fortnight since, to hear a lecture on the novel and interesting operation of lithotrity, and to witness the performance of the operation on several patients by Mr. Costello. On Thursday there seemed to be no abatement of the interest excited on the occasion, as the medical gentlemen assembled in still greater numbers, and from greater distances than at first, to witness the continuation of the operations. Practitioners were present from Bedford, Newport Pagnel, Stony Stratford, Wellingborough, Kettering, Thrapston, Oundle, Market Harborough, Leicester, Daventry, Banbury, Towcester, Leamington, and some even from Birmingham. At two o'clock Dr. Robertson was called to the chair. On taking the chair Dr. R. dwelt on the pleasure which the meeting had felt on the former occasion, in hearing from Mr. Costello his clear and able narrative of facts, bearing upon the discovery and successful establishment of this important improvement—the most important—of modern surgery. Seeing so many gentlemen present on this, who were not able to attend on the former occasion, he hoped Mr. Costello would not think it too much trouble to enter briefly upon some of those points of the medical literature of lithotrity, previously to the performance of the

operations. The board room of the Infirmary was crowded, and the interest at this moment was intense. Mr. Costello undertook the task, and performed it in a fluent, clear, and impressive manner, shedding over the inductions and details of science the graces of easy and natural eloquence. He observed, that nothing could be more interesting to the medical man of the present day, than to consider separately the history of any operation or curative process, from its earliest period down to its present state. By way of elucidation he made a rapid sketch of amputation, tracing it through its phases of actual cautery, ligature, union by first intention, &c. He followed out the history of lithotrixy in the same manner, dwelling forcibly and learnedly on the various attempts which had been made, in the progress of ages, to supersede the operation by the knife. He alluded with gratitude to the labours of Civiale, who was the first to establish this beneficent and almost painless mode of operation; and concluded his luminous address, which was frequently interrupted by the applause of the meeting, by stating that the popularity of lithotrixy was founded on the benefits it had already conferred on suffering humanity, as evinced in upwards of 300 cases of cure.—One of the patients was now introduced and placed on the table. There was none of the terror in the countenance of the patient, nor anxiety in that of the operator, which the by-stander is wont to associate with the idea of a great surgical operation. The patient was smiling and apparently unconcerned; the operator calm and cheerful. His dexterity was truly admirable; in a twinkling the stone was seized, and was distinctly heard to break down under Mr. C's rapid manipulation. The instrument was now withdrawn, and passed round for inspection; its jaws were loaded with the debris of the poor patient's internal enemy. He got off the table nimbly, and it was highly pleasing to hear him, turning towards Mr. Costello, with a tear swelling in his eye,

exclaim, "Ah, sir, I wish I had something to give you."—Another patient was now placed on the table, when Mr. Costello facetiously remarked, "this is our old friend, Jack Robinson." In this case there was but a small fragment remaining, which for a short time seemed to elude the grasp of the instrument, which made Mr. Costello observe, while he still continued his search, that "some pockets were not so easily picked as others;" it was now secured and destroyed in a moment. At the termination of the operations the rounds of applause were deafening.

The following series of resolutions were afterwards passed by the meeting.

It was moved by Wm. Percival, Esq., of Northampton, seconded by H. Terry, Esq., of Northampton, and resolved unanimously,

1st. That the thanks of this meeting be given to Mr. Costello, with the strongest assurances of the great pleasure the meeting have felt in witnessing the very able and satisfactory manner in which he has gone through with the novel and interesting operations performed this day.

It was moved by Dr. Witt, of Bedford, seconded by H. L. Smith, Esq., of Southam, and resolved unanimously,

2nd. That this meeting cordially and entirely approves of the following resolution, passed at the meeting, held at this Infirmary, on the 5th instant, viz.:—"That this meeting, taking into mature consideration the nature and bearings of the dispute betwixt the Governors of the Aldersgate-street Dispensary and the Medical Officers of that Institution, is unequivocally of opinion, that the said Officers have vindicated their own honour and the honour and dignity of the medical profession in the noblest manner, by resisting a regulation which strikes at the root of honourable and talented competition for medical officers, and opens the door to ill-disguised venality and intrigue. This meeting is furthermore of opinion, that the late Medical Officers of the Aldersgate-street Dispensary, by the spirited and independent manner in which they have acted, are well entitled to the support and sympathy, the thanks and applause, the approbation and admiration, of the profession at large."

It was moved by John Harris, Esq. of Bedford, seconded by Wm. Jones,

Esq. of Lutterworth, and resolved unanimously,

3rd. That, in reference to the Aldersgate-street business, this meeting observes, with regret, that the Governors still adhere to the pernicious and derogatory regulation complained of by their late Medical Officers; and that, after making a parade of their philanthropy, and of their tender regard for the distressed objects of the Institution, the said Governors have thought fit to elect the first and only medical men that offered themselves for the appointments.

This meeting furthermore laments, that any medical men should have been found capable of accepting the vacant offices, conscious, as they must be, that they have so accepted them in defiance of the honest opinion of their professional brethren throughout the empire, extensively expressed, and all but universally felt.

It was moved by H. Terry, Esq. of Northampton, seconded by Thomas Parker, Esq. of Woburn, and resolved unanimously,

4th. That this meeting also take the present opportunity of tendering their thanks to their medical brethren in Sheffield, for the very laudable and necessary remonstrance they lately addressed to the Governors of the Dispensary of that place, touching the admission of patients, in point of circumstances not proper objects of charity—a matter which this meeting views as of vital detriment to the interests and welfare of the medical profession, and of charities in general.

It was moved by H. L. Smith, Esq. of Southam, seconded by D. Boulton, Esq. of Leamington, and resolved unanimously.

5th. That these resolutions be communicated to the weekly medical publications, and to the newspapers.

It was moved by Dr. Witt, of Bedford, seconded by John Horwood, Esq. of Northampton, and resolved unanimously.

6th. That the thanks of this meeting be given to Dr. Robertson for his conduct in the chair.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, October 28, 1833.

WILLIAM KINGDON, Esq., President, in the Chair.

Pathology of Cholera.

Mr. Proctor observed that it would be very desirable to ascertain the opinions of the society on the treatment of malignant cholera, so that in the event of the reappearance of the disease, practitioners might have some certain method of treating it. There were many gentlemen present who had seen it during the last and the present year. According to his observation, there were three distinct diseases prevalent this year; diarrhoea, English cholera, and malignant cholera. He believed the last was Asiatic and contagious. He had seen four cases in which the patients had dined on beef steaks and mutton chops, and died in four or six hours afterwards.

Mr. Stephens described the derangement of the digestive system which was very general during the epidemic influenza in 1832 and 33, which consisted in rumbling in the bowels as if about to be purged, slight numbness in the superior and inferior extremities, oppression of the heart, intermitting pulse, and tendency to syncope, which last several days. He was desirous to learn if others had observed these symptoms.

Dr. Johnson felt surprised that Mr. Proctor considered the three diseases he had mentioned as distinct, as the majority of the profession considered them stages of the epidemic cholera. The symptoms described by Mr. Stephens were almost universally present both in 1832 and 33, and attacked those who had escaped as well as those who had suffered from the disease.

Mr. Hooper could not agree to the sentiments of Mr. Proctor, while he fully concurred with those expressed by Dr. Johnson and Mr. Stephens.

Mr. Headland expressed his dissent from the notion that a correct treatment could be discovered while

the real cause of cholera was undecided. He mentioned a case in which he and three other practitioners attended, and each had his peculiar views; but the patient recovered.

Dr. Williams agreed with Mr. Headland that as yet the cause of the cholera was undecided, and that he should like to be informed on the diagnosis of the disease.

Dr. Uwins said that he and Dr. Johnson had done more for the treatment and suppression of the disease improperly called cholera, by destroying cholera phobia, than most other practitioners. He had seen several cases five months before the advocates of contagion would allow that the disease existed in this country; and one of the cases was also observed by Mr. Owen of Holborn. The term cholera as applied to this and what was called the English disease was absurd.

Dr. Negri stated that the diarrhoea which preceded cholera was characteristic, it was accompanied by a peculiar expression of countenance, a glazed and slightly bloodshot eye, coldness in the abdomen, and the other symptoms described by Mr. Stephens. The cholera belonged to the same genus as the febris perniciosa cholericæ described by Torti, and he had endeavoured to show the connection in a letter which he had published and addressed to Dr. Barry. In one case of choleric diarrhoea, he had ordered six grains of calomel and a draught composed of magnesia and rhubarb with water, he had given two other doses and the disease had ceased. The symptomatology of cholera was diversified, and no plan of treatment as yet proposed was generally successful.

Dr. Shearman said that no such disease as the malignant cholera had occurred during his observation, which was extended to a period of between forty and fifty years. He agreed with those who held it important to determine its cause before a plan of treatment was proposed.

Dr. Walshman considered it most important to dilute the fluid which was so copiously secreted, either

with cold water or chicken tea, as he had found this plan of great service in English cholera.

Dr. Uwins proposed that a special general meeting of the society be held on Monday next, to consider the subject of the late proceedings at the Aldersgate-street Dispensary.

Dr. Waller seconded the proposal, and it was carried unanimously.

THE

London Medical & Surgical Journal

Saturday, November 2, 1833.

MEETING OF THE WESTMINSTER MEDICAL SOCIETY. — VOTE OF THANKS TO THE LATE MEDICAL OFFICERS OF THE LATE ALDERSGATE-STREET DISPENSARY.

WE announced in our last number that the Westminster Medical Society would, at their next meeting, take into their consideration the conduct of the late medical officers of the late Aldersgate-street Dispensary.

The meeting took place on Saturday last, and was the fullest attended we recollect to have seen in our experience*.

* There are no less than nine hundred members of the medical profession belonging to this society, and there are but few, if any, names of practitioners of repute in this large city which are not enrolled upon its books. From its great numbers, from the respectability of its members, from the general scrutiny it exercises over the affairs of the medical profession, and from the influence which its discussions have upon the character and future prospects of the medical body, it ranks, in our eyes, as a kind of reformed Medical House of Commons. In fact this large voluntary association, governed by the will of the majority, and enjoying perfect freedom of debate, may be considered as embodying in the general tone of its sentiments, the thoughts and feelings of the liberal part of the profession in this country upon all questions of medical ethics or politics. It is therefore with no slight satisfaction that we contemplate its late proceedings upon the subject which has latterly occupied so much of our attention.

It has been truly said that the daily press in this country is but the organ of public opinion,

Dr. Epps, with singular magnanimity, opposed the general feeling of the Society on the question. We refer with pleasure to the striking and just remarks of Dr. Sigmond, in reply to the strange charge of inconsistency against the late medical officers. Dr. Epps is of opinion, that these gentlemen were, as lawyers say, *estopped* from objecting to the fraud being practised for the future, because some of them, it seems, from his information, were cognisant of the fraud at former elections. In the same manner the College of Physicians have, at times, tried to gag a noisy licentiate who might have dared to object to their darling and *insolent* monopoly (as we shall prove in good time), by quoting against him his declared acquiescence in their laws. Thus ever does use sanction abuse. Subject to this little exception, the proceedings of the meeting (reported in another place of this Journal) were dignified and unanimous.

**MEDICAL REFORM.—TACTICS OF THE
COLLEGE OF PHYSICIANS.—THE
APOTHECARIES.**

It is singular to observe what important changes in the legal constitution

and it almost invariably follows, where shallow reasoners persuade themselves it leads,—the sentiments of the thinking public. In the same spirit we, as journalists, shall be more proud of the justice of our strictures, and their consonance with the general judgment of the profession, than captivated by the charms of mere originality.

The discussion on Saturday night has, in a measure, wound up the Aldersgate-street affair. The gentlemen who so honourably resigned have received their highest applause, from the largest and most influential body of their brethren in the kingdom; and those who have distinguished themselves by the force of contrast, “verily, they have *their* reward.”

of the medical profession have been set afloat by the attempt of the profession in Scotland to obtain a little bit of legislation in their own behalf. So anomalous, so contradictory, so absurd, is the system under which admittance to the profession is regulated, —such discontent was engendered by its insulting distinction of ranks—that the medical institutions had actually arrived at that stage of climacteric disease, as Sir Henry Halford calls it, when the slightest movement was enough to disjoint the whole.

We shall have frequent occasion to enlarge upon the causes of this rapid decay in foundations laid,—some would fondly hope,—for perpetuity. The history of the past contains a lesson for the future; we shall hereafter find “meat for the strong” in certain legal struggles of the College of Physicians with volunteers from among the licentiates, in courts of justice. Their triumphs upon these occasions, by means of legal technicalities, have bolstered up that overweening self-confidence, which they cannot even yet bring themselves to renounce. The sun of corporation absurdities has set; the day when every by-law was *tolerated*, because it was *barely legal*, has passed away; and, with improvements occurring around us, far surpassing even the visions of those who dreamed of the perfectibility of man, it is cheering to conclude, that the time is not far distant, when the medical profession will be legislated for, according to its vital importance to society; and that, what once depended upon the acci-

dental influence of a favourite physician with a minister, will become the bounden duty of a reformed House of Commons. Assured are we, that Linacre and Harvey would rejoice to see the College they dignified, accommodated to the spirit of the times, if indeed its present rotten state was ever contemplated by its founders.

Meantime the *vis inertiae* of the College is overcome. We understand that, a few days ago, Sir Henry Hallford and the Fellows of the College of Physicians forwarded a memorial, through Lord Melbourne, praying for power to grant medical degrees in London, in competition with the Universities of Oxford and Cambridge. This was met by a counter-memorial of the Licentiates, praying for an inquiry into and reform of abuses. Nothing is to be done without the knowledge of the Licentiates ;—and, in the nineteenth century, we may, without much risk, go farther, and say, Nothing *shall* be done, until a thorough investigation of the whole state of the medical profession in the three kingdoms shall have taken place : and, so much more is there to be accomplished, in restraining the mal-practitioner, than a King's charter, in the plenitude of its power, can effect, that an Act of Parliament will be, more than probably, the charter of our rights and privileges. The time for palliatives is gone by. A prudent alteration of its odious by-laws might have formerly satisfied the wants of the public, and the desires of the profession.

These overtures of the College arise from some rumours that it was the

intention of the ruling powers to give the London University the power of conferring degrees in medicine. We believe the subject is receiving the serious consideration of the government. If we did not see a plain necessity for a still broader and more durable arrangement, there is no existing body of whose medical department we have a higher opinion, or to whom we would more willingly trust such a serious duty.

SCHISM IN THE ROYAL COLLEGE OF SURGEONS.

WE have heard that a serious misunderstanding has occurred at a late meeting of the Council of the Royal College of Surgeons. Some of the members were contending that there should be two examinations,—one for members or consulting surgeons, and another for lecturers. The subject was so warmly discussed, that six of the Council retired, and declared they would not attend another meeting. We regret that any such contest should have occurred.

GENEROSITY.

A good man delights to have an opportunity of doing good suggested to him. We understand Minter Hart is in "durance vile," one of his coadjutors being already sentenced to transportation. Ought not Dr. Ramadge, in return for past services, to assist him with some part of our £ 400 ? A friend in need is a friend indeed.

UNIVERSITY OF EDINBURGH.

AN impression has gone abroad, and has gained strength from certain recent discussions in the Town Council, that our University is in a declining state, and in particular, that, as a Medical School, it is losing the high status which it once held in public estimation. The statement, if true, is one in which the inhabitants at large are interested. Education and Law are the two staple occupations by which the town subsists, and if these fail us, where shall we find a substitute? In estimating the condition of a university, some persons think merely of the eminence of the professors; and the deceptions, arising from the uncertainty of this in itself, are increased by associations connecting themselves with the changes which inevitably take place. A professor, for instance, is gathered to his fathers at the ripe age of seventy or eighty, with the accumulated fame of half a century on his head, and is succeeded by a young man of whom the world has heard nothing. This is the course of nature, and the change wears the aspect of a declension at the moment when it occurs, though, in point of fact, the illustrious deceased was perhaps as much overshadowed by the merit of his predecessor when he first obtained the chair, as the present occupier; and the latter though appointed amidst evil auguries and forebodings, may, in his turn, be deplored at his death, as an irreparable loss to the seminary. In general no safe conclusions can be drawn from such uncertain data; and the true test of the prosperity of a university is to be found in the number of students who attend it. Now, when we apply this standard to our Medical School, we shall find the result the very reverse of discouraging. The question is one of fact; and that we might proceed on sure grounds, we have procured from an authentic source, returns of the number of Medical Students who matriculated and graduated at our

college for a series of years, and we here present them as briefly as we can.

I. Dividing the forty years from 1790 to 1830 into the periods of ten years, the average number who matriculated annually, was as follows—

	Average Matriculations.
1790 to 1800	560
1800 to 1810	739
1810 to 1820	828
1820 to 1830	839

II. If without striking an average, we take five single years at intervals of ten years from each other, the result is similar.

	Matriculated.
The Session 1790-1	517
1799-1800	636
1809-10	876
1829-30	896

III. We shall now give a table of the average graduations for periods of ten years, from the institution of the Medical Faculty in 1726. This will show the number of students who completed their medical education here.

	Average Graduations.
1726 to 1738	2
1740 to 1750	5
1750 to 1760	10
1760 to 1770	12
1770 to 1780	21
1780 to 1790	28
1790 to 1800	39
1800 to 1810	49
1810 to 1820	84
1820 to 1830	113

These tables, we think, are not less satisfactory than conclusive. Our University has been like an oak, of slow but regular growth, possessing a firmness and strength which has enabled it to move onward in a course of prosperity, unaffected by the moral and political changes which were constantly occurring. Let us be careful to keep it, by judicious reforms, on a level with the state of science, and the wants of society, and we need have no fear for its future success.—*From a Correspondent.*

MISCELLANIES.

BATH MEDICAL SOCIETY.—At a special general meeting of the Bath Medical Society, Dr. Barlow in the chair, Dr. Daniell was elected President for the ensuing year.

A general meeting of the apothecaries of Ireland is to take place in Dublin, the 19th of next month, on the projected change in the law regulating pharmacy.

The various classes in the University of Edinburgh, for the season, commence the 5th of next month.

BIRMINGHAM DISPENSARY.—On Wednesday a special general meeting of the Governors of the Dispensary was held for the election of a physician in the room of Dr. Eccles, recently appointed to the General Hospital. Drs. Hamett and Huey having withdrawn, the only candidates were Drs. Lloyd and Evans. On the chair being taken by the Rev. John Kentish, a vote of thanks was passed to Dr. Eccles for his valuable services to the charity during the sixteen years he had held the appointment. Dr. Lloyd and Dr. Evans were next reported by the medical officers of the charity to be duly qualified; and the former gentleman was proposed by the Rev. Edward Burn, seconded by P. M. James, Esq.; the latter by Mr. Whateley, seconded by Mr. Wm. Wills. The ballot then commenced, and continued until two o'clock, when the numbers were declared—

For Dr. Lloyd—Present 165
Proxies 30

— 195
For Dr. Evans—Present 80
Proxies 55

— 135
Majority for Dr. Lloyd — 60

who was accordingly declared duly elected. Thanks were then voted to the chairman, and the meeting separated.—*Birmingham Paper of Monday, Oct. 28.*

PROFESSOR TRAILL.—Dr. Thomas Traill, Professor of Medical Juris-

prudence in the University of Edinburgh, lately paid a visit to Orkney, his native county. A number of gentlemen, chiefly his school-fellows and early associates, being desirous to evince the high respect and esteem which they entertained for his worth, talents, and scientific acquirements, invited him to a public breakfast in Macdonald's Inn, Kirkwall, on the 10th current, when he was presented with a handsome piece of plate, bearing the following inscription:—
"Presented to Dr. Thomas Traill, Professor of Medical Jurisprudence in the University of Edinburgh, F.R.S.E. Mem. Wer. Soc., F. Geol. Soc. Lond., Mem. Royal Min. Soc. Dresden, &c., &c., on his visit to Orkney after an absence of 29 years, by a few Friends and Contemporaries, in testimony of their high regard for his private worth, respect for his talents and professional and scientific attainments, and of their gratification at the honour which has, through him, been reflected on their common country."
—September, 1833.

Portuguese Hospital Reports.

To the Editors of the *London Medical and Surgical Journal*.

GENTLEMEN,—I have the honour of forwarding to you some of the many cases that came under my observation at Oporto, where I had the good fortune to be stationed during the siege of that city by the Miguelites. When I acknowledge that I had every access to the Military Hospitals there, and that I attended them with some attention and diligence, you will be surprised to find my cases so few and so little interesting. But of those I saw at the Hospital of the English Brigade, for many reasons the chief object of my visit, I shall publish none, as the more interesting cases treated there will be laid before the public by a more able pen than mine.

I owed the privilege of attending the British Hospital to Mr. Rutherford Alcock, the talented staff surgeon

of the English Brigade, whom I here warmly thank for his constant kindness and liberality to me, and in doing this I represent, I am sure, the feelings of all my brethren connected with the English squadron in the Douro, all of whom experienced from Mr. Alcock the same kind and liberal behaviour.

I need not say, that these cases are wholly at your disposal. You may publish them all, a part, or none of them.

I have the honour to be,
Gentlemen,
Your obedient and humble servant,
JOHN REES,
Assistant Surgeon, R.N.

*H. M. S. Orestes,
Portsmouth, Oct. 14, 1833.*

Simple Fracture.—Amputation.

Jan. 27. Senhor Thomas Bento, the clerk of a Portuguese merchant of Villa Nova, a man of 43 years of age, and of regular habits, broke his leg the 27th of December, 1832. He met with this misfortune by falling over a cliff, when in the act of running away from a shell that threatened to burst near him. His first medical attendant was a Miguelite regimental surgeon, who applied splints to his leg, &c, and visited him regularly for about a month, when, considering his case to be incurable, he deserted him, with a strong advice to call immediately to his aid one of the "Holy Fathers." Not being able to communicate with Oporto, on account of the siege, and having broken his leg when on the business of supplying the British squadron with provisions, he applied for surgical assistance to Captain Glascock of H. M. S. Orestes, the senior officer of the Douro squadron. Mr. Monteith, surgeon of the Orestes, and myself went immediately to see him. He was attended by an old woman, who anointed his leg with oil and crammed his stomach with chicken-broth, the diet of all sick people in Portugal, whatever their age or the nature of their disease. We found him extremely reduced ;

pulse 120, and feeble ; tongue loaded, and brown at the root ; no appetite ; bowels regular. The bones were fractured about the insertion of the Ligamentum patellæ. Not the slightest union had taken place, and on each side of the leg, at the seat of the fracture, was an ulcerated opening, whence discharged a great quantity of thin, dark, and fœtid matter, which evidently came from the interior of the knee-joint, and from abscesses around and about it.

Amputation being the only means that promised him a chance of recovery, the limb was removed the following day by Mr. Monteith. The patient bore his sufferings very well, and lost very little blood ; he, however, became very faint at the conclusion of the operation, but by giving him a little wine, and putting him in bed he was soon revived. To be kept perfectly quiet, to have chicken-broth in moderate quantities, and 3ss. of t. opii. h. s.

Examination of the Leg after amputation.—The knee-joint was greatly diseased, hardly any traces remained of the outer articular cartilages, and the articulating ends of the bones were denuded of their cartilages almost entirely. The bones, to some extent at their fractured ends, were denuded of periosteum, and there existed no signs of any attempt at uniting the fracture.

Jan. 28th. Slept well all night ; says he feels much better. Pulse only 106, and of a more favourable character. Has had no starting or pain in the stump. There has been a little hæmorrhage about the end of the bone. The stump to be kept wet with cold water. The same diet to be continued, and repeat tinct. opii.

29th. Passed a good night ; has no fever ; pulse 112. There has been a little more bleeding at the same spot. The same treatment to be continued, but to omit tinct. opii.

30th. Did not sleep so well ; in other respects is the same as yesterday ; no more bleeding. To continue

the same diet and cold application, and to have a common enema.

31st. Slept better; bowels purged twice; the state of his system in other respects the same as yesterday; complains of pain and heat in the stump. Opened the stump; about a third has apparently united; the un-united part is opposite the bone, where the bleeding was, whence was discharged some matter mixed with blood. Omit cold water to stump; continue the same diet.

Feb. 1st. Slept badly on account of pain in the stump; bowels open; pulse the same; a considerable discharge from the stump; matter thin, and of a rather unhealthy colour; parts that appeared united yesterday are gaping to day; only about half an inch at the right corner now united. The same diet to be continued.

2nd. Slept pretty well; in other respects is the same as yesterday, but discharge from the stump is less, and of a better quality. To continue the chicken broth diet, and to have 3oz. of port wine daily.

3rd. Is worse to day; slept very badly; is a little feverish; pulse 122; bowels rather loose, with some griping pain; state of the stump the same. Omit wine; continue the same diet. Pil. hyd. gr. iv., Opii, gr. i., P. rhei, gr. vj., nocte.

4th. Is better; slept pretty well; bowels open; pulse the same; says he has a good appetite coming on; discharge from stump the same; no more union. Dressed the stump with compresses so placed as to keep the flaps in close contact, and to allow of no retention of matter within. Cap. Quin. sulph. gr. i., ter in die. The same diet, and to have some jellies; some meat also for dinner.

5th. Better in all respects; pulse only 100; no matter retained in the stump, and the whole appears to have united, excepting at the situation of the ligatures; the stump was dressed the same manner as yesterday. To continue the same diet; and sulph. quiniæ.

8th. Stump has been daily dressed; which as well as his general health, continued improving until last night, when he became a little feverish, and had pain in the stump; slept badly; more matter than usual discharged to day from the corners, the situation of the ligatures opposite the bone; the flaps have gaped, and there was discharged thence a tablespoonful of matter mixed with blood. Applied pressure by compresses above and below at each corner, and as I considered the mischief at the bone to proceed from the bleeding of a vessel in a cavity, I applied to the end of the bone gentle pressure, by means of a soft compress. To continue the same treatment.

9th. Feels better. Very slight discharge and no bleeding. Continue the same remedies and diet.

11th. Very little discharge yesterday. Omitted the compress at the end of the bone. A considerable discharge to-day, particularly from the situation of the end of the bone; also some hæmorrhage from that situation. Is a little feverish. Ligatures came away; replaced the compress at the end of the bone. Continue the quinine and the same diet.

18th. Continued to improve until yesterday, when the stump was all but healed. Edges have since gaped at the corners and at the end of the bone. Discharge considerable. Was feverish last night, and is so to-day; bowels regular; pulse 112. Has not been guilty of any irregularity so far as I can ascertain. Stump to be dressed as before, and to continue the same diet and medicines.

19th. Much better to-day; pulse 104; very little discharge. The same treatment to be continued, &c.

From this period he continued slowly improving, both as to his general health and the state of his stump. By the 12th of March he was quite well and his stump perfectly healed.

(To be continued.)

French Medicine.

Scirrhus of the Superior Portion of the Œsophagus.—M. G., æt. 46, had been suffering for four or five years from an affection of the throat, for the relief of which all remedies had been unavailing. She was of a highly susceptible and nervous temperament, and was at times subject to slight attacks of hysteria. The sound of her voice betrayed the presence and irritation of a foreign body in the throat, keeping up a spasmodic action of the muscles of the part, which, when controlled, caused no pain on pressure being made over the anterior and lateral parts of the neck.

Her nights were sleepless from the constant desire to cough up the mucus deposited on what she supposed was the seat of the affection, the irritation of which was always greater when she lay down to rest. On examining the interior of the mouth, the mucous membrane covering the velum, palate, and pharynx, was found inflamed, but not sufficiently so to form the sole cause of the affection. There was no tumour to be seen or felt on the external surface of the larynx. Pressure over these parts gave no pain. The sound of the voice was not remarkably altered; she could raise or depress it without causing much cough, or spasmodic action, which would not have been the case if the larynx had been at all implicated in the affliction. She had been bled generally and locally: counter-irritation had been employed over the affected part, and she used gargles of various kinds without any relief. A seton in the neck had been proposed, but to this she would not submit. It was then determined to try the effect of blowing fine alum powder into the throat, which considerably increased all her former sufferings. The expectorated mucus was slightly tinged with blood, which had not been remarked before using the alum powder. A seton was now made in the neck, which, after discharging for a month, had afforded no relief, and

which was therefore dried up. The power of performing deglutition had greatly decreased, and she could, with difficulty, swallow fluids, which caused great irritation. This difficulty increased daily, and the body wasted in proportion from want of nourishment.

An œsophagus tube was endeavoured to be passed into the stomach, but was found impracticable.

She now placed herself under the care of another medical man, but he was unable to relieve her, and she died.

Autopsy.—The lungs were healthy; the mucous membrane of the bronchiæ, larynx, velum palati, and pharynx presented slight traces of phlogosis; the sub-mucous cellular tissue was slightly infiltrated; the trachea contained a small quantity of viscid mucus, but the harder textures of the larynx were in their normal state. At the upper part of the œsophagus was a scirrhus tumour about three inches in length; it was cylindrical in shape, and formed in the muscular structure of the part; its thickness was from four to five lines posteriorly, and somewhat less anteriorly; it had grown from without inwards, and had so narrowed the calibre of the œsophagus, that a director could scarcely pass. The mucous membrane immediately around the tumour presented no traces of disorganisation, and there was no exterior adhesion between the scirrhus tumour and the surrounding tissues. At the upper portion of the tumour there were three or four irregular and ulcerated excavations having a cancerous appearance; these probably had been caused by the use of the alum. The tumour was of a cartilaginous consistence, and of the colour of the white of an egg. The pectoral portion of the œsophagus was in a normal state. The appearance of the body generally was that of extreme marasmus.—*Gaz. Méd.*

Division of the Symphysis Pubis.—M. Bandeloque has recently performed this operation with perfect success both to mother and child.

Dislocation of the Humerus backwards.—M. Sedillot, surgeon at the Val de Grace, has met with a case of luxation of the humerus backwards into the fossa infra spinata, which was reduced a year and fifteen days after the accident took place. This dislocation is so rare, that Desault never saw a case, and Boyer mentions only one.

NATIONAL ASSOCIATION OF THE APOTHECARIES IN IRELAND.—VIEWS OF THE GOVERNMENT ON MEDICAL REFORM.

A DEPUTATION of the National Association of the Apothecaries in Ireland waited on Mr. Littleton, the Government Secretary, a few days since, and begged to be informed of the nature of those reforms contemplated by the administration, in respect to the medical professions of Great Britain, &c.

Mr. Littleton stated, that this extensive and important subject was still open to investigation. After giving it the best consideration, it had appeared prudent to defer the enactment of any partial measures, and he (Mr. Littleton) fully expected that a motion would be made early in the next session of parliament for a select committee of the House, with full powers to obtain all necessary evidence, to enable parliament to legislate consistently and comprehensively. He thought it highly probable, that ultimately three separate Bills would be enacted, to regulate the professions of physicians, surgeons, and apothecaries, each of which should contain a distinct and uniform code for each particular profession.

Mr. Littleton assured the deputation, that the Government was justly desirous to aid in placing the medical profession on the most respectable and consistent basis, but, at the same time, felt that the subject needed much open investigation, to enable the legislature to take decided and permanently useful steps in the business.

After some further conversation on

this important subject, in which Mr. Littleton appeared anxious to meet the general views of the profession on this topic.

The deputation withdrew.

Phosphorus has been tried.

The address of the profession at Nottingham to the late medical officers of the Aldersgate-street Dispensary in our next.

J. W. R.—The object in view would be obtained without residence at Erlangen.

A Westminster Hospital Student.—The piracy of Mr. Guthrie's excellent Lectures on the Diseases of the Urinary Organs is too bare-faced to require a single comment. It shows how hard up our contemporary is for matter, when he hashes up, without acknowledgment, the lectures which appeared in this Journal. As to Mr. Edwards, "the puffer-general of Baron Heurteloup," we shall pass him by, but we shall keep an eye upon him. We are aware of his friendly feelings, and duly appreciate them. The present opportunity enables us to assure the Editor of the *Satirist*, that we did not allude to him when we used the term—"Calumniators of Mr. Guthrie." In fact, there are some persons who are in the habit of sucking Mr. Guthrie's brains, and then defaming him in the immaculate pages of a contemporary. These we designated calumniators.

A. Z., a Birmingham Subscriber; A Friend in Liverpool; A Student at King's College; A General Practitioner; M. H.; Scotus.—The lectures will appear in future as often as convenience will permit.

Books in our next.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXII., DELIVERED MARCH 4, 1833.

GENTLEMEN,—In the last lecture I drew your attention to some of the causes of necrosis, amongst which were those of a mechanical nature. Here is a fine specimen of a necrosis which was the consequence of a mechanical injury, namely, a fracture, and where you see that the dead bone is surrounded by a great quantity of new osseous matter. The technical term given by pathologists to the dead bone, so circumstanced, is the *sequestrum*. On one side of the new bony case you may observe several apertures, through which the matter, formed in the interior, is discharged, and hence they receive the appellation of *cloacæ*. The nature of these apertures I will explain more fully hereafter. The preparation, which I now show you, is an example of a necrosis consequent to a surgical operation. Necrosis of the femur, after amputation of the thigh, is by no means an uncommon case; and it is certainly possible that, in the instance before us, as well as in others, the disease for which amputation had been performed, might have extended its effects into the medullary membrane higher up than where the bone was sawn; but, on other occasions, you will find what remains of the shaft of the bone is attacked with necrosis; though it was sound at the period of the operation: this happens when the stump becomes much diseased and large abscesses form in it;—then the bone becomes affected secondarily. In the instance before us, you see that the necrosis has extended as high up as the trochanters, and even partly involves the head of the femur, which is not an ordinary occurrence. Gun-shot wounds frequently give rise to necrosis. In the preparation, which I will now pass round for your inspection, you may see a remarkably

white portion of bone; that is the dead part—the *sequestrum*, as it is termed: the necrosis was produced by a gun-shot injury.

With regard to the symptoms of necrosis, gentlemen, I may observe, that they vary in different cases, according to the extent of the disease and the nature of its cause. When the necrosis is of limited extent, that is, when the affection is merely superficial, not extending deeply into the bone, and arising in consequence of external violence, the symptoms will not be very different from those of a common phlegmonous abscess. Suppuration occurs in the soft parts, and, as soon as the matter is discharged, if you introduce a probe, you will feel the bare bone. In such a case, unless there be an extensive and violent inflammation of the soft parts, there may be little or no constitutional disturbance; but when the necrosis is more considerable, and the soft parts are more extensively implicated, either primarily or secondarily, in the disorder, then there will be a greater, and sometimes a violent, derangement of the system. But there is a form of necrosis—one, in which the patient is generally young and of a scrofulous habit of body, and in which the bones of the carpus, or tarsus, or the phalanges of the fingers, suffer. In such cases, in general, an indolent swelling first forms, unattended with much pain or disturbance of the system; at length a fluid collects in the part, which bursts, and pours out an ichorous matter. In this stage of the disease, if you introduce a probe, you may feel the bone to be bare and rough—in fact, it is already in the state of necrosis. It is chiefly in individuals, thus predisposed to the disease, that we meet with those formidable examples of necrosis, in which the whole shaft of a long cylindrical bone perishes. In scrofulous or syphilitic persons, on the application of some exciting cause, the death of the whole shaft of a long bone, or a considerable portion of some other bone, frequently occurs, as you may observe in this preparation, where you see the whole shaft of the tibia has perished. When the disease arises in individuals, whose state of constitution promotes the origin and wide spread of disease in the osseous system, necrosis generally begins with a deep-seated

and excruciating pain in the limb, followed by a general swelling, involving the whole of that part of the member, and mostly including also the two nearest joints. It is, however, much greater about the centre of the limb than elsewhere; and one of its characters is, that it seems to have no definite boundary, presenting everywhere a remarkably firm unyielding feel. The patient experiences no alleviation of his sufferings till matter forms and the abscess bursts, and then there is generally some diminution of the pain; but, it is found that, on the escape of the matter the tumour does not subside in the degree usually remarked in a common abscess under similar circumstances; there still remains an immense swelling, which is of a very firm unyielding kind, depending upon the great quantity of coagulable lymph effused around the dead bone, and the thickened and oedematous state of the cellular membrane. These circumstances explain why there is very little subsidence of the swelling immediately after the matter has been let out, or made an outlet for itself. If you introduce a probe after the bursting of the abscess, you will generally find that it passes onwards till it is stopped by the bone, a portion of which may often be felt to be bare and rough. In these cases I recommend you to let out the matter early, for the sooner this is done the sooner will the patient experience a diminution of the agony attending the confinement of deep-seated matter. After the abscess has made its way out, or been discharged by puncture, the opening or openings (for there are sometimes more than one) will not heal up very speedily; in fact, they are mostly converted into fistulae, and, losing all disposition to cicatrize, they emit fungous granulations around their orifices. The indisposition of these fistulae to heal, however, does not usually depend upon any other impediment than the presence of the dead bone in the limb, the sequestrum, which, in the manner of an extraneous body, keeps up irritation and suppuration. Hence, nature seems to maintain the fistulous apertures, in order that whatever pus is formed may flow out, and sometimes, as experience proves, for the passage of the dead bone itself. In consequence of the presence of the sequestrum and the long-continued suppuration thereby produced, the sympathetic inflammatory fever, which attends the first stages of an extensive necrosis, is soon converted into a febrile disturbance of the hectic type; indeed, the disease generally goes on so long, and the discharge sometimes continues for such an indefinite length of time, that the constitution may be reduced to the lowest state of weakness; and, in addition to the hectic, there are occasional attacks of irritative fever, by which the patient is brought into great danger, such danger as admits of no means for its removal except an operation for the extraction of the sequestrum, the cause of all this suffering and peril; or if the disease be

not in a state for such proceeding, you may feel yourself called upon to perform amputation of the limb, in order to save the patient's life. Where the patient's health is sinking fast, and he appears incapable of sustaining a longer struggle with the local disease, which is acting as the cause of all the constitutional disturbance, your only resource is either to make an effort to extract the sequestrum, or else to take off the limb; the decision will often require all your judgment, and is sometimes a delicate and difficult duty. Before you can say positively that necrosis exists, it is necessary to introduce a probe, for until you can touch a portion of dead bone, you cannot be certain that the disease has occurred. Sometimes, however, when the dead portion of bone lies superficially, you may actually see a part of it within the fistula, or at the bottom of an ulcerated chasm. Gentlemen, you should recollect that the colour of a sequestrum is not always the same; it is often perfectly white; and when you see a portion of bone whiter than natural, you may be sure that it is in the state of necrosis. Generally when the dead bone has been exposed for some time to the air, it becomes black, and every body knows that a bone with this appearance has perished. In particular instances, where the whiteness may not be much increased, there may be doubt; but if you observe a brown tinge upon the exposed bone, you may conclude that it is dead. Excessive whiteness, or a darker colour than natural, is a sure indication of necrosis. Here, gentlemen, is a beautiful specimen of a white sequestrum. I should wish you to remember, that the colour of the sequestrum depends very much on two circumstances; when it lies deep, and is not exposed to the air, it is generally white, or of a light brown colour; but when it has been exposed for some time to the atmosphere, or has lain long at the bottom of an open ulcer, it assumes a darkish and even a black hue.

Now, gentlemen, the process of *exfoliation*, or that process by which the dead portion of bone is separated from the living portion, requires a few observations. It has a considerable resemblance to the process by which sloughs of the soft parts are thrown off; especially this will seem the case, if you make due allowance for the greater slowness with which all changes in the bones are carried on. If you examine this skull-cap, which I will pass round, you will see that a groove has been formed all round the sequestrum, which is generally believed by pathologists to have been produced by the action of the absorbents of the adjoining living bone, which once surrounded it. The groove begins on the surface, and extends gradually deeper and deeper, until the dead portion is completely undermined and detached; in this respect you will recognise also a correspondence to what happens in the separation of sloughs. In another skull before us, on which there are

several exfoliations taking place, you will remark a curious circumstance, namely, one sequestrum is actually wedged in between the two tables of the cranium, and would therefore have required the removal of a portion of the external table, ere it could have been taken away. Here is a good specimen of a dark coloured sequestrum, which also illustrates another fact, namely, that a sequestrum is frequently grooved and irregular on its surface, a circumstance which is accounted for by some pathologists as the result of the action of the absorbents of the living upon the dead bone; a doctrine, however, which I observe is not very much respected in some of the Edinburgh schools. Indeed, you will sometimes find that a sequestrum is reduced to an inconsiderable size, compared with what it was originally; in fact, sometimes the greater part of it is removed, and unless it come away in minute particles with the discharge, I know of no agents for the production of this change, but those busy workmen, the absorbents.

In the earliest stage of necrosis, the periosteum (if spared), in the neighbourhood of the portion of bone about to be destroyed, always becomes thickened and more vascular than natural, and continues in this state during the formation of the substitute for the old bone; but as soon as this process is finished, and particularly after the detachment of the sequestrum, the periosteum returns to its natural condition, and loses its increased vascularity; its inner surface has no longer the pulpy, granular, highly vascular texture which it had in the early stages of the case, when the office of producing the new bony formation round the sequestrum devolved upon it. After the sequestrum has been completely loosened, it still remains at the bottom of the abscess or ulcer, or within the new bony case, and would sometimes continue there a considerable time, keeping up pain, irritation, and discharge, were you not to introduce your forceps and remove it, and even to make such incisions for the purpose, and such removal of a part of the new deposit of bone, as may be requisite. Occasionally the sequestrum is not only perfectly loose, but so superficial and exposed, that it can be taken away without any occasion for the knife, trephine, or saw. When an abscess, ulcer, or fistula, is complicated with dead bone, it is a rule in surgery always to remove the sequestrum as soon as possible, that is, as soon as it is loose, and for this purpose to practise such operations as may be necessary. But not only is the sequestrum often loosened and thrown off from the living bone by spontaneous or natural processes, (and I have seen several cases in which considerable portions of the shafts of the humerus and femur have been thus detached, coming out through the integuments without the aid of any formal surgical operation,) not only does nature effect all this, but when the entire shaft of a

bone has been destroyed, she makes wonderful and generally most successful efforts to form a new bone, that answers almost as well as the original one. When the shafts of the tibia, humerus, femur, or other long cylindrical bones, are destroyed, and nothing of the original bone remains alive, except the articular extremities, (for I mentioned to you in the last lecture, that though the whole shaft of a bone be destroyed by necrosis, yet the articular heads are generally spared;) even when the destruction has proceeded to this extent, nature will form a new bone, and the uses of the part or limb will be restored. You see in the preparation which I now place before you, an instance in which the whole shaft of the tibia has been destroyed, and a considerable portion of it removed, probably by absorption; that a new osseous tube has been formed completely round the sequestrum; you also see in the sides of the new bony formation the openings, termed the *cloacæ*, which serve, as I have already explained, for the escape of the matter, which is generally secreted in the interior of the new bone, as long as the sequestrum keeps up irritation there. The *cloacæ* in many instances take an oblique course, and do not pass straight and direct into the cavity of the osseous tube. They mostly have an oval or a round shape. Some of these before us appear to pass direct into the cavity of the new bone; a fact not agreeing exactly with Weidmann's description, whose account of this subject is only surpassed by what nature herself reveals. No doubt, the straight direct course of the *cloacæ* before us, is an exception to the general rule. The flat, as well as the cylindrical bones, when attacked with necrosis, possess the power of reproduction; there are several cases on record, in which the scapula has been reproduced, after suffering necrosis; and it is known, that portions of the os cranium, under particular circumstances, may also be regenerated. Instances are related, where nearly the whole of a parietal bone has been reproduced. Considering the little reparation which losses of portions of the skull from the trephine, or external violence, undergo, this is what we should not *a priori* expect; yet we know, that in the museum of this university, there is a remarkable preparation, the skull of a person who had been trephined forty years before his death, and a considerable portion of bone taken away, which has in a great measure been restored. Generally, the reproduction of bone after trephining does not happen to any great extent; the pericranium being destroyed and both the tables of the skull being removed, the reparation is very partial. It appears, therefore, that the dura mater does not possess the power of reproducing bone at all equal to that of the pericranium, or periosteum of the bones in general; however, if only the outer table be removed, the diploe and the dura mater together, will effect the reproduction of the lost portion; but, in other instances, you will rarely find, that any very successful

attempt is made by nature for the restoration of the two destroyed tables. Even fractures of the skull are alleged to unite with difficulty and slowness. The preparation I am speaking of, I regard as a particularly interesting one; in all probability, at the time of the operation, the patient was young, perhaps a child; this I infer from the circumstance of his having been trephined forty years before his death; now, in young growing subjects, you will find the power of reproduction in bones is always considerably greater than in older persons.

Gentlemen, though the long, cylindrical, and flat bones, may be regenerated, the short cuboid bones cannot be reproduced. When once destroyed, there can be no restoration of them; this fact is one, which all men of experience are fully aware of. In the early periods of life, as I have mentioned, and in healthy subjects, the power of reproduction in bones is always greater than in old or debilitated persons. The power of reproduction is also seriously diminished in particular states of the constitution, and especially when the individual is under the influence of lues venerea, at least the worst forms of it, cancer, scurvy, and rickets. I believe, however, that some of these constitutional diseases do not absolutely prevent the reproduction of bone in every instance; and that exceptions are met with, in which broken bones unite more or less completely in spite of them.

Now, gentlemen, the next subject respecting necrosis, is a very curious and interesting one, I allude to the means adopted by nature to bring about the reproduction of bone. Of this part of the inquiry different pathologists give different accounts, proving that further investigations into certain points would be desirable; my own views I will presently explain. The questions are, whether nature accomplishes her purpose by means of the vessels of the periosteum? by means of those of the medullary membrane? or in another manner, in which it is supposed, that, when the whole shaft of a bone has been reproduced, the inner portion of the bone alone has perished, and that the outer one has been saved and transformed into the new shaft? This last opinion is maintained by some men of considerable eminence both in France and Scotland. They assert, that, in necrosis, the whole of the bone does not really perish; that the outer portion is preserved; and, that, when the whole shaft seems to have been reproduced, it is in consequence of the external lamina separating from the inner ones, which alone are truly destroyed. That the latter representation is not applicable to a great number of instances, I consider perfectly certain; but whether it is *ever* really the case, is another question.

Dr. Macdonald, who investigated this subject with considerable talent, found, that the new bone actually began to form previously to the complete death of the old one. Both he and Professor Russell observed, that, during the formation of the new bone, they could

inject the vessels of the old one. These circumstances as far as they go, would strengthen the doctrine I have adverted to, as one prevalent both in France and Scotland, namely, that the old bone is the source of the new one. The supporters of this doctrine have recourse likewise to another circumstance, as an argument in favour of their view, they take advantage of the fact, that, in all, or almost all, cases where new long cylindrical bones are formed, the articular heads are saved, so that these preserved portions must be regarded as contributing also to the formation of the new bone. But, this doctrine certainly cannot apply to other instances, in which the whole shaft of the bone is known to have been destroyed, through its entire thickness. Cases are continually presenting themselves, in which from the thickness of the sequestrum, there can be no doubt of the whole substance and diameter of the original bone having perished. Then, how would the suggested theory explain the reproduction of portions of the whole thickness of the tibia sawn away, or lost by the effect of external violence? Indeed, the careful observation and correct examination of the different stages of the process of reproduction, tend to prove, that, at all events, in some cases the periosteum has a principal share in the formation of the new osseous matter; for it is found to become thickened and more vascular than natural; to assume a pulpy granular texture internally; a new kind of organisation, fitting it for its increased duty, the cellular membrane external to it also becoming swollen. In the museum of St. Bartholomew's Hospital are some preparations, put up by Dr. Macartney of Dublin, exhibiting these facts. The periosteum then separates from the portion of bone, which is about to perish, and becomes covered internally with a vascular pulpy substance, that is destined for the secretion of the new bone, the nidus for which is no doubt at first coagulable lymph. Such are the processes which probably always take place when the whole shaft of a bone perishes; they seem to happen also very early; for, in one instance, which Dr. Macartney had an opportunity of examining in an incipient stage, the separation of the periosteum had taken place, though there was only a small abscess formed in the medullary membrane. With respect to the changes which are preparatory to a deposit of new bone, they are an increased thickness of the periosteum, and an increased vascularity of it and of the adjoining cellular substance. These facts admit of demonstration—they may be seen—and, I have no doubt, that any gentleman who may wish to study the preparations illustrative of them in the museum of St. Bartholomew's hospital, would be permitted to examine them on mentioning my name either to Mr. Lawrence or Mr. Stanley. Indeed those preparations completely refute the doctrine, which maintains exclusively that the old bone is invariably the organ by which all the new shaft is produced. I do not mean to say, that there may not be

cases, in which the internal portion perishes and the outer portion lives, any more than that there may not be instances, in which the destruction is confined to the outer lamina; we know that these last cases are common enough, in relation to the destruction of a certain extent of almost any bone. Experiments have been made on animals, which tend also to prove the fact of the periosteum being often actively concerned in the reproduction of bone; every part of the bone has been removed, all the medullary membrane, and the whole of the osseous texture have been taken away, in order to ascertain whether the periosteum was capable of restoring the lost substance; these experiments confirm the views I have given you on the subject. Some of them were made by Troja and others by Koehler, to whose respective works I must refer you.

Gentlemen, there is another point, on which very different opinions are entertained by different pathologists. When the periosteum has formed the new bone, what becomes of it? Dr. Macartney describes the periosteum as being removed after performing that office, and the cellular membrane on the outside of it as being converted into a new periosteum. This seems to be rather improbable, for, after the new bone has been formed, it must still require a supply of blood for its nutrition, the same as during its formation; and the vessels of the new bone being connected with those of the original periosteum, it is difficult to conceive why the circulation should not continue to be carried on through that medium. I may also mention, in relation to this fact, that in the Museum of St. Bartholomew's Hospital there are preparations, in which the periosteum of the new bone is seen to be continuous with that of the articular extremities of the old one, a consideration, I think, very much against the hypothesis of the removal of the old periosteum. This and other minute circumstances I look upon as demanding further investigation.

The internal surface of the new bony case forms a tube, lined with a vascular pulpy substance, which becomes a membrane. The dead shaft, or portion of bone that has perished, as I have said, is called the *sequestrum*; and in the osseous case, there are always one or more, sometimes seven or eight, apertures for the passage of purulent matter and fragments of bone out of the space between the sequestrum and the new bony formation. These apertures, you will remember, are called *cloacæ*, as I have already told you. Experience has proved, that the sequestrum gradually undergoes, when long retained, a change in its shape and size; but this change is one of considerable slowness; indeed, the total absorption of the sequestrum would sometimes require so long a period, that the patient would hardly live till the completion of the process. In children it goes on more quickly and with greater success. The absorption of the sequestrum is probably effected by the absorb-

ents of the vascular substance between the sequestrum and the new bony tube. In the living subject, you will not find the dead portion of bone so loose within the new case as it is in the preparations I have shown you; in fact, the space between the old and new bone is occupied by the pulpy vascular substance I have mentioned. As the new osseous formation is produced before the removal of the old bone, and is external to it, of course it must be larger and more clumsy than the original one. You see an illustration of this circumstance in the preparation which I now pass to you. The old bone appears, then, to serve as a kind of model for the new one, and in time, after the sequestrum has been entirely removed, the irregularities on the surface of the new bone are gradually smoothed down, and its thickness diminishes, so that it becomes as nearly as possible of the size and shape of the original bone. One most curious fact is, that during the whole of the processes by which an original bone is destroyed and regenerated, it rarely happens that any want of firmness in the limb is experienced; it is not flexible; there is no shortening of it; and, what is equally remarkable, the attachments of all the muscles are preserved as in their original state, a fact, which, I think, proves the truth of the opinion, that the old periosteum remains.

Gentlemen, notwithstanding what has been stated, you may meet with an uncommon sort of case, in which the new bone is not thrown out fast enough to prevent a shortening of the limb. There was an instance at St. Bartholomew's Hospital, a few years ago, of the femur being destroyed by necrosis, and the new bone not being secreted with sufficient quickness and perfection to prevent a retraction of the limb. In that case, amputation was performed, and the preparation is now placed in the Museum of St. Bartholomew's Hospital.

On Wednesday, gentlemen, I shall direct your attention to the *treatment of necrosis*, and to some other subjects connected with this very curious and interesting disease.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

At the Meath Hospital, or County of Dublin Infirmary, Session 1832-33.

LECTURE XVII.

Pathology of Inflammation.

GENTLEMEN,—At my last lecture I drew your attention to the doctrines of revulsion and of sympathies, and pointed out the great practical advantages which result from a careful consideration of morbid sympathies. I mentioned that the improvement in medicine, consequent on the study of sympathies, may be considered in a double point of view. In the first place

It gives us a clear insight into the connexion of diseases, and enables us to form an idea when there is one disease existing in the system, how another may supervene; we are also led to suspect what the secondary and subsequent affection may be, and in many instances are able to employ preventive measures with effect. In the next place, we are taught that long-continued sympathetic irritation is very apt to terminate in organic disease. You observe, gentlemen, the great practical importance of this law; it strongly inculcates a most essential rule in practice, namely, that when an organ has been sympathetically affected for a long time, the probabilities are that there is more or less of organic change, and that it would, in many instances, be dangerous to treat a chronic affection otherwise than as a case of real organic disease.

We come now to one of the most important parts of the doctrine of Broussais, his theory of inflammation. His opinions on this subject may be expressed in a very few words. He does not seek to explain the different modifications and forms of inflammation as many others have endeavoured to do, he only attempts to prove that the inflammatory affection of any organ is to be considered as a plus degree of the vitality of that organ. This is all he essayed to prove; he has not advanced a single step further. I have already alluded to this, and shown that mere difference in degree will not explain the various forms of disease. And though it may be difficult to demonstrate the difference between the physiological and pathological excitement of an organ, yet that there is an essential difference is shown by their results and effects on the constitution. But what he has chiefly effected, and the benefits which he has particularly conferred on practical medicine consist in the very important announcement, that a great majority of local diseases are referable to an inflammatory process, that a vast number of affections, not previously supposed to depend on inflammation, are really inflammatory, and that we may have *intense local inflammation in a worn and debilitated constitution*. If Broussais's services had been nothing more than drawing the attention of the medical world to the inflammatory nature of numberless diseases, previously looked upon as non-inflammatory, he would be most justly entitled to the most unequivocal praise. He certainly has the honour of having first pointed out the connexion of an enormous group of diseases with inflammation, and has clearly demonstrated the existence of increased vascular action in cases where it was before totally unsuspected. He has shown, that many instances of cerebral disease are intimately connected with an inflammatory process, and gives various instances of epilepsy, mania, delirium, and apoplexy, in which there was distinct proof of vascular excitement of the brain. He does not pretend to say, that in all and every case of cerebral affection there is an active deter-

mination of blood to the brain, requiring antiphlogistic treatment, but he asserts and proves, that such is the case in a great many instances. Again, he has shown that a carditis may produce disease of the valves and hypertrophy; he has demonstrated the connexion between inflammation and organic disease of the aorta, and hence has demonstrated the very close link between aortic inflammation and aneurism. With respect to the lungs, Broussais deserves the credit of having developed most of our information on the subjects of pneumonia, bronchitis, and pleurisy, and has shown the intimate connexion between tubercles and inflammation. To this I have alluded in a former lecture. I do not agree with Broussais in thinking that tubercles are always the result of an inflammatory process; but however this may be, it is certain, that, in many instances, tubercular development is preceded by inflammation, that it is accompanied by inflammation, that its progress is accelerated by an inflammatory condition, and that the principles of its treatment are those which are calculated to remove congestion and inflammation of the pulmonary tissue. He has also connected the growth of a variety of other morbid productions in the lung with inflammation; and, although I do not go so far as to admit his theory, which makes all such growths depend on inflammation, still I think the principles which have been applied to the treatment of tubercles are admissible here as in cases of cancer or hydatids. Broussais has certainly done a great deal in developing the history of latent disease of the lungs, and has given most valuable hints for the treatment of sympathetic derangements of these organs, a class of diseases which was previously but very little understood. He has shown, that many cases of apparently intense pulmonic derangement are only to be relieved by treatment directed to the stomach, or some other organ. Our true knowledge of the nature of asthma and whooping-cough is due to him; for he has shown that many cases of disease of the chest, supposed to be spasmodic, are complicated with more or less of inflammation and organic change.

We come now to his discoveries in the pathology of the digestive system. One of the most interesting illustrations of disease of the intestinal tube is this, that we may have extensive inflammation of some part of it without any pain being complained of by the patient. Now the painless character of such affections was first noticed by M. Broussais; it was he who first demonstrated the falsity of a doctrine, long prevailing among medical men, that pain was necessarily connected with inflammation. It is an undoubted fact, that some of the worst forms of inflammation may occur without the co-existence of pain. The idea which the older authors had of enteritis was, that it was an inflammatory condition of the intestinal tube, accompanied by severe pain, and cases of this painless enteritis were generally looked upon as instances of essential

fever. According to their actions enteritis not only consisted in inflammation of the mucous membrane of the intestines, but also of their muscular and peritoneal investments, and they were not aware that inflammation might be confined to the mucous membrane and mucous glands, and that there cannot be a more important or more frequent form of disease. I think we may safely affirm, that the best and greatest part of our information, on the subject of enteric inflammation, is due to Broussais; and when we remember what a vast proportion of persons die of enteritis, that it occurs in every degree of violence and intensity, that the digestive system is the main-spring of our very existence, the fountain on which the economy depends for nutrition and repair; when we reflect upon this, and consider that almost all our knowledge of the affections of a system, so important to life, is due to M. Broussais, we must confess that he has effected much for the advancement of science.

Let us take a brief review of the phenomena of disease in different parts of the digestive tube. In the first place, with respect to diseases of the œsophagus, many affections, before now considered to depend on spasm and nervous derangement, are at present found to have a close connexion with inflammation. Stricture of the œsophagus is now proved to arise in various instances from inflammation of the submucous tissue; this it is of importance to be acquainted with. In the next place it has been established, that in the stomach we may have innumerable shades of inflammatory action, and that in the great proportion of dyspeptic cases of any standing there is more or less of gastritis. I believe Broussais has gone too far, in saying that all cases of dyspepsia are cases of gastric inflammation; but I am convinced that many of them are essentially of an inflammatory character, and I think it would be well for the public if British practitioners were more thoroughly acquainted with this fact. It would frequently enable them to trace the flatus, anorexia, and pain, to their true cause, gastric inflammation, and not to some unknown condition of the nervous coat of the stomach. Viewing the subject in this light, the physician will not commit the fatal error of aggravating a case of dyspepsia connected with gastritis, by administering tonics, stimulants, or purgatives, nor will he by injudicious treatment bring on fatal organic disease of the stomach. It is now established (and our knowledge is derived from the same source), that many cases of cancer of the stomach have commenced by simple inflammation, and hence it is that Broussais looks on such cases as only instances of an aggravated chronic gastritis. I do not know whether this be true or not, but I believe it is certain that many of them are such, and that in their progress there is more or less inflammation present, and that the most decided benefit is frequently derived from local antiphlogistic means.

When we come to the duodenum, we find that the discoveries of Broussais are equally valuable, and that very little was known respecting its pathology until he threw light upon it. Many cases of jaundice otherwise obscure, are explained by a knowledge of the inflammatory affections of this part of the digestive tube. Bichat was the first person who pointed out the strong sympathy which exists between the mucous membrane of the duodenum and the excretory ducts of the liver and pancreas, but it was Broussais who taught the doctrine, that jaundice without accompanying symptoms of hepatitis most commonly depends on inflammation of the duodenum. This explains the complication of jaundice with the occurrence of gastro-duodenal inflammation, and gives a most important key to the treatment of such affections. Another discovery of Broussais, the value of which cannot be sufficiently appreciated, is, that inflammation of the upper part of the digestive tube is a common cause of constipation, and that the constipation is in proportion to the gastro-duodenal affection. You perceive of what importance this view of the subject is, and you can conceive how hazardous it would be to attempt to remove this by purgation, that is, by the employment of a direct revulsive stimulus. I shall not comment on the purgative practice generally followed in these countries, in the treatment of every form of dyspepsia.

With respect to hypochondriasis, and some affections of the liver, he is also of opinion that most of these depend on inflammation, and are frequently the consequence of a gastro-duodenitis. This is not necessarily true, nor do I think it has been sufficiently proved. Yet I believe that we may frequently find a gastro-duodenal inflammation combined with hepatic disease, and that in many of these cases it would be improper to attempt to relieve the affection of the liver by purgatives.

Until the publication of Broussais' work, *tabes mesenterica* was supposed to be an original scrofulous disorganisation of the mesenteric glands, but he has shown that the enlargement and obstruction of the glands is often secondary to inflammatory disease of the mucous membrane of the intestines, or in other words, that the enlargement of those glands resembles the buboes which appear in the groin as a consequence of chancre on the penis. The old practice in the treatment of this disease, was to give medicines which were supposed to be possessed of a solvent or de-obstruent property, and it was customary to employ alkalies, lime water, and other substances which were considered to be capable of removing the obstruction. It however unfortunately happened, that many of those remedies having a direct stimulant effect, only increased the mischief by irritating an already diseased intestinal surface. Broussais' views of *tabes mesenterica* were essentially different. He considered the disease as an original in-

inflammatory affection of the mucous crypts and surface of the intestinal tube. This, in the first place, points out the most rational principles of treatment and cure in the incipient stage, and even in an incurable case indicates that mode of practice which is devoid of danger and likely to give relief. In almost all cases of tabes, you will find that the disease has commenced with symptoms of enteritis, or what has been termed infantile remittent fever. Are we, then, to consider all cases of tabes mesenterica as secondary and dependent on an original inflammation of the intestinal mucous membrane? I believe not. There are cases in which we find scrofulous matter deposited in various parts of the mesenteric glandular system, without the co-existence of mucous inflammation of the intestines, but these are exceptions, and the pathology which I have given furnishes us with the general rule in the consideration and treatment of this form of disease. By far the most common cause of tabes mesenterica is primitive inflammation of the mucous follicles and membrane which lines the intestinal canal.

With respect to *melæna*, intestinal hæmorrhage, diarrhoea, and dysentery, and also stricture of the intestines, ascites, and disease of the kidneys, Broussais, by showing their close connexion with inflammatory action, has furnished us with a key to their treatment, which had been previously conducted in an empirical manner. For instance, we used before now to give purgatives in dysentery, under the erroneous impression that the disease was produced and kept up by retained scybala; this is no longer the practice: mild laxatives are used where necessary, but the disease is considered and treated as a colitis. It is unnecessary for me to pursue this subject any further, and I shall only remark, that by demonstrating the inflammatory nature of most organic diseases, he has added immensely to the value of medicine, and furnished a great many new hints to the treatment and prevention of disease.

Now, let us ask ourselves this question. When we consider the present state of medical science, and compare it with what it was fifty years ago, when we observe the vast improvements in practice, and the vast number of diseases previously considered obscure and intractable which are now well understood and successfully treated, where are we to seek for the source and origin of all these valuable additions to our knowledge? You will, I think, on reflection, be inclined to own that all or nearly all our improvements in medical science, that is to say, all our improved treatment of disease, arises from the discovery, that most organic diseases are in their nature inflammatory, or if not so at first, still that the probability of an inflammatory complication during the progress of the affection is exceedingly strong. Let us take a few examples. Convulsions have been treated in different ways; by stimulants, opiates, and antispas-

modics, and the irritation of the brain and spinal marrow were too often overlooked. Without going so far as to say that all cases of convulsions depend on inflammation of these organs, it is certain that it frequently exists, that irritation of such important parts should never be totally neglected, and that in the majority of cases it will be safer and better to direct our treatment to the spine and head than to trust to antispasmodics. Again, hydrocephalus was supposed to be a species of dropsical effusion, unaccompanied by active inflammation, and diuretics and purgatives were administered for the purpose of removing it. What is the practice at present? Leeches, cold affusions, mercury, every thing calculated to remove congestion and inflammation from the system. To what is the improvement in the treatment of dyspepsia owing? We have got no new specific, no panacea adapted to all its Protean shades of character. Still we treat it now with better success and less empiricism than formerly, and why? Because we no longer look upon all cases of dyspepsia as mere nervous derangement, unaware that in nine cases out of ten, where the disease has been of any considerable duration, there was more or less gastritis. How many cases of hysteria and supposed disease of the heart, are now found to depend on spinal irritation? How many of the complex and puzzling affections of females are now found to be benefited and relieved by local antiphlogistic means? Has not a knowledge of the inflammatory complications of whooping cough thrown a vast deal of light on its treatment? Is not the modern treatment of hydrothorax, by means calculated to remove local inflammation, infinitely more successful than the old plan of diuretics and expectorants? Look to skin diseases: our predecessors were not happy in the management of these affections; at present we are very successful, because in treating them we always keep their inflammatory nature in view. Who is there now, who is not aware of the advantages of bleeding from the arm in many cases of psoriasis, and leeching the penis in many instances of syphilitic inflammation? We treat arthritis at present better than it was done formerly, because we trust less to specifics, and are more aware of its inflammatory character. Neither are we so fond of purgatives as we used to be, for we know that they are irritating and stimulant, and highly objectionable in many states of the intestinal canal. In decrying purgative medicine Broussais went too far, but, doubtless, if he has given too little, we have used them far too abundantly. An eminent physician told me, that after the publication of Hamilton's work on purgative medicines, strictures of the rectum and colon became much more frequent. There are very few diseases in which our knowledge of a primary or subsequent inflammatory condition has not been productive of the most beneficial results.

Gentlemen, I come now to speak of Broussais's theory of fever. I have told you on a former occasion that his doctrine on this subject

is, that there is no such thing as essential fever, and that all fevers are symptomatic of *some local disease*. We shall consider this theory in three points of view; first with respect to the exanthemata, next to intermittent, and lastly to continued, fever.

Previously to the publication of Broussais's opinions, the exanthemata were commonly looked upon as mere affections of the skin. This was the idea which generally prevailed on the subject, and I regret to state that it has not as yet been entirely discarded. Broussais, however, has proved that the exanthematous eruption is only secondary, that the first morbid action is on the viscera, and that if we consider them as merely skin diseases, we take a very imperfect and limited view. I believe that the whole of the improvement in the treatment of the exanthemata consists in the attention to the state of the viscera. When a person dies of measles, he certainly does not die of skin disease, it is some visceral affection which proves fatal. The results of the case are in exact proportion to the healthy or unhealthy state of the viscera, and it is to these that our attention must be particularly directed. There are two periods when the viscera are most likely to be affected, before the eruption comes out, and when it begins to decline. Sometimes the viscera are violently attacked in the commencement, the eruption does not appear, and the patient dies of pneumonia or some other inflammation. Again the danger is very great at the subsidence of the cutaneous affection. We are, therefore, to look upon the eruption as only a link in the chain of phenomena, and sedulously attend to the condition of the viscera, as it is upon this the fortunate or fatal termination of the disease more immediately depends. It was to this point Broussais particularly directed the attention of medical practitioners, and though he may not have the honour of originating the improvement, still he has the merit of having been the first who strongly impressed on the minds of medical men the important fact that life or death, a safe and speedy, or a tedious and doubtful convalescence, depends, not on the state of the cutaneous eruption, but on the healthy or morbid condition of the viscera.

Broussais's theory of fever has been the great stumbling block to the progress and due estimation of his improvements, because it has not been able to stand the test of rigorous examination, and has been disproved by the stubborn authority of facts. His theory of fever may be expressed in two propositions; first, that fever is always sympathetic of some local lesion; and in the next place, that typhus is only the sympathy of a constitution with a gastro-enteritis. Before I enter upon the consideration of the question, whether typhus is to be considered only as a gastro-enteritis, I shall make a few remarks on fever in general. Broussais has not discovered, nor indeed has he made any attempt to discover, the proximate cause of fever, and our knowledge of its actual nature is

now just what it was in the time of Hippocrates. But our acquaintance with its phenomena and treatment is vastly increased, and it consists in the knowledge of this important fact that simple, essential fever without any local lesion is an exceedingly rare occurrence. Mere fever, without organic or visceral disease, is very seldom met with. It is true we frequently hear of persons dying of fever, but if we investigate such cases we shall find that death has been produced by some visceral disease, and I believe that it may be stated as an undoubted fact, that in very many cases, on opening the body of a patient who has died of what is termed fever, visceral lesions will be detected sufficient to account for death, if fever had not existed at all. Go round the wards of a fever hospital and examine all the patients, and you will be convinced how few are the cases which are unaccompanied by visceral disease. One has symptoms of disease of the brain, another has the cough, lividity, and respiration of bronchitis, another has the signs of abdominal irritation, pain in the belly, diarrhoea, and foetid stools, another exhibits all the phenomena of pneumonia, and some present decided indications of disease of the three great cavities. Go next to the dead room and inspect bodies, and you will find unequivocal marks of every form of visceral inflammation. Andral gives an account of the post mortem examinations of fifty persons who died of fever; in three-fifths of these there was disease of the intestines sufficient to account for death; in the remaining two-fifths, three had erysipelas of the lower extremities, two had arachnitis, two croup, one hepatisation of the lungs, four had disease of the stomach, and in four more the lungs, liver, and spleen, were filled with hydatids. Now considering fever as a general affection combined with local lesions, which are generally the cause of death, we arrive at a grand principle of treatment, and for this, I must say, we are indebted to Broussais. It shows us that *it is to the local affections which arise during the course, and modify the progress and cure, of a fever, that we are chiefly to attend*. We perceive that nature is frequently prevented from bringing about a favourable crisis by the presence of some acute local affection, we reduce this, and by doing so, gain several advantages; we moderate the fever, we diminish the liability to new local disease, and give, as it were, fair play to the operations of nature. We prevent the lesions from becoming so violent as to prove dangerous, and thus do all that human aid can effect in bringing on a favourable termination. These are the principles which flow from Broussais's doctrine of the localisation of disease. A most beautiful deduction from this view of the subject is one which is, perhaps, not sufficiently known, namely, that what is called crisis in fever almost invariably depends on the reduction of local inflammation. What prevents the occurrence of crisis in almost every case? Acute local inflammation. Remove this, and the

crisis appears. I have frequently directed your attention to this in our clinical practice, and shall say nothing more on the subject. You may, however, see from this, that in the treatment of fever you should not attempt to force a crisis;—the true mode of bringing it about is to reduce local inflammation, and endeavour to keep the viscera in a healthy state. The practice, too often employed, of attempting to force it by diaphoretic medicines is opposed to common sense and sound pathology. The great general improvement in the modern treatment of fever is, that antiphlogistics are at present much more extensively employed than stimulants. Before the publication of Broussais's discovery it was too commonly the practice to have recourse to stimulants during the whole course of the disease; but, at present, every judicious physician uses antiphlogistic means, at least in the commencement, and will not resort to stimulants until the vital powers begin to sink. It is a common opinion, and one which I am sorry to say some medical teachers are in the habit of impressing on their pupils, that opposite modes of treatment will often do equally well in fever, and that Dr. A. who gives wine, Dr. B. who bleeds, and Dr. C. who purges, will be alike successful. This I do not deny may be true in a few instances; there is an endless variety in the nature of fever; and a bleeding doctor might lose a patient which another might cure by giving wine and stimulants. But, until it is shown that brandy and bark are capable of removing a gastritis, a pneumonia, or an irritation of the brain, or that bleeding will improve a debilitated frame, we are, I think, to look on such declarations as an outrage on common sense.

A few words now with respect to the theory that typhus is nothing but a gastro-enteritis. Broussais sought for the anatomical characters of this kind of fever, and, as he most generally found those to exist in the intestinal tube, he fell into the erroneous opinion, that typhus was only sympathetic of a gastro-enteritis. Physiologists have, however, rejected this doctrine for the following reasons. In the first place, it is an established fact, that we may have fatal typhus without any perceptible alteration of the intestinal canal. This single fact is sufficient to disprove the whole theory. In the next place, it has been proved that there is no constant relation between the amount of intestinal disease and the fever,—that is to say, that in some cases we may have a fatal typhus with very little disease of the intestines, and *vice versa*. Thirdly, in many cases of gastro-enteritis there is no typhus fever at all. Fourthly, it has been proved, that the introduction of poisonous substances into the blood of animals is capable of producing symptoms of typhus and disease of the stomach and intestines. Lastly, instances of typhus are frequently observed in which the morbid state of the system is removed by treatment not at all calculated to cure disease

of the mucous membrane of the stomach and bowels. This part of Broussais's theory is therefore no longer tenable, and must be given up. Still, much good has been effected by drawing the attention of medical men to the very frequent occurrence of gastro-enteritis in fever. It appears, indeed, to be an exceedingly common affection; and though we cannot cure every fever, still we can alleviate and remove a great many by treatment directed to the stomach and bowels. Broussais has also made a precious addition to the stock of our knowledge, by showing that intestinal inflammation may come on in a latent insidious manner, without pain or the usual phenomena of the disease; and he has developed the symptoms of this form of inflammation in an ingenious and able manner. One of his most interesting discoveries is, that where, during the course of a fever, secondary inflammation sets in so as to form an unfavourable complication, and retard the appearance of crisis, if you remove the inflammation you will often be able to succeed in curing the fever. This is a fact of undeniable importance.

Before I conclude, I shall make a few observations with respect to a very strong objection which may be urged against the doctrines of Broussais. He has fallen into a great error, in supposing that *inflammatory affections demand an antiphlogistic treatment in all periods of their course and progress*; in other words, he has not recognised the fact, that there is a time when disease is not to be removed by ordinary antiphlogistics, and that, under such circumstances, *stimulants are in reality antiphlogistics*. This he seems to have overlooked. Yet, when we look at inflammation in any part of the system, we find that it is characterised at two different periods by extremely diverse conditions, one requiring an antiphlogistic treatment, the other a stimulant. Broussais has certainly done much to improve our knowledge in managing the first stage, but has, unfortunately, neglected the last, or that which has been described as the stage of *asthenia hyperæmia*. His impression was, that all forms of inflammation yield to antiphlogistic remedies, not reflecting, that even when we succeed in removing an inflammatory affection by constant depletion, we may purchase the cure at a very dear price. We are all aware, that in a case of psoriasis the antiphlogistic treatment is at first essentially necessary; but we are not to infer from this that it will be equally efficient in every stage of the disease. The time will come, when venesection, leeches, and purgatives must be given up, and a stimulant plan of treatment adopted. The same rule holds good in cases of conjunctival inflammation, of tinea capitis, and many other complaints having an inflammatory origin. In the advanced stage of a bronchitis we do not attempt to effect a cure by depletion; we prescribe a good nutritious diet, and stimulating, expectorant, and diaphoretic medicines. It is in the recognition of this second condition that

much of the value of practical medicine depends; and this rule applies not only to affections of the membranes, but also to those of the viscera. Andral gives a very valuable suggestion on this point. He is inclined to think, that the good effect of stimulants, in the advanced stage of fever, may arise from the existing asthenic condition of the whole system, and there is much ingenuity and justice in the supposition.

Gentlemen, this concludes what I had to observe on the theory and doctrines of Broussais. I have laid before you a brief, but, I trust, intelligible exposition of his principal opinions, and have endeavoured to show where he has been successful and where he has fallen into error. He found medicine in a state of chaos, and attempted to reduce it to order. His talents were undoubtedly great, and his discoveries of the deepest importance; but he went too far, in thinking that he could explain every variety of typhus fever by referring it to the existence of a manifest or concealed gastro-enteritis. He fell into the great error of proving too much. He also displayed some of the arrogance which is the besetting sin of theorists and dogmatists; he had not enough of the modesty which should characterise science, and his fate will be a warning hereafter to speculative individuals, never to sacrifice truth to theory, or to place opinions in array against the overpowering evidence of facts.

Gentlemen, I have now finished, and must return thanks for your attention. Our session has been an interesting one. We have had a great many valuable cases in the hospital; the industrious have had ample opportunities of acquiring the most important part of professional knowledge; and I am proud to say, that it has never been my lot to meet with a more intelligent and gentleman-like class. The friendship which we have formed will, I trust, not soon subside, and believe me, gentlemen, I shall long and affectionately remember the class of 1832-33.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital, Oct. 30th.

LECTURE VI.

On the Anatomy and Diseases of the Bladder and Urethra.

GENTLEMEN,—What is the urethra? This question, I presume, you all think you can answer without a moment's hesitation. It is, however, a most difficult one, which I cannot solve without some circumlocution. Is it the canal itself through which the urine passes? Upon that point you will say there is no doubt;

but is it not also the wall which bounds and forms the canal? Is not the word used surgically in that sense? You will admit this also without hesitation; and now then, gentlemen, will any of you tell me of what the wall, or substance which forms the tube, is composed? Be pleased to read over the last twenty authors who have written on the subject, and you will not find two of them quite agreeing in opinion; some say it is one thing, some another, and others shirk the inquiry altogether; yet it is a very important one with relation to the means to be adopted for the cure of some of the diseases which affect it. It is admitted by all parties, that the inner lining is cuticular, and covering a mucous membrane, which is also elastic, and endowed with great and peculiar sensibility. But some, with Mr. Hunter, Sir E. Home and Mr. Wilson, suppose this to be a muscular coat also, composed of muscular fibres, so small as scarcely to be detected by the microscope, and united to each other by mucus instead of tendons, a state which may exist, but which I do not comprehend. Others, again, consider these muscular stræ to be merely a vascular arrangement, or to be the elastic fibres of the membrane itself. All parties, however, appear to me to consider the wall of the canal to be similarly composed in its whole length, which I apprehend to be a source of error, there being three great divisions, very differently circumstanced as to structure with relation to the surrounding parts. These three divisions are the prostatic, the membranous, and the bulbous and spongy parts of the canal. The two first I have described; and your attention will at once be drawn most forcibly to the great difference which exists between them, when I state to you a fact which is acknowledged by almost all surgeons of experience, namely, that the prostatic and membranous parts are not the seat of stricture, which is confined to the anterior part of the urethra, or that portion which is co-existing with, and anterior to, the triangular ligament, and is called the bulbous and spongy part. The membranous part of the urethra is so called, I believe, because it may by dissection be readily reduced to its internal membrane alone. I have demonstrated to you a peculiar muscle which surrounds it, which I have no doubt compresses and closes it so as to act as a sphincter, the true nature of which had been overlooked; but the contraction of this muscle which surrounds this part of the urethra in so evident and perfect a manner does not give rise to permanent stricture. It may compress any thing introduced into the canal and flatten it; it may render it impervious when strongly excited, but it does not remain permanently contracted, or give rise to continued stricture or obstruction. The urethra at this part, membranous as I have described it to be, and capable of being reduced to a single layer of mucous tissue, is not applied in this state to the inside of the muscle. There is a quantity

of condensed cellular and fibrous structure between them, so that the wall of the canal is not only here composed of a cuticular, a mucous, and a vascular layer, but of an external covering of fibro-cellular structure, something resembling the coat of an artery, and by which it is connected to the sphincter or compressor muscle. It passes through the triangular ligament in this state to meet the bulbous portion of the urethra, and it is rarely, except when it meets with this, or is surrounded by the corpus spongiosum, that strictures are found in disease. It appears therefore a reasonable deduction, that it is in consequence of something which is added, rather than on account of something which is taken away, that this propensity to disease takes place.

I have described to you with some precision the origin and attachments of the accelerator urinæ muscle, and particularly that part of it which surrounds the urethra immediately anterior to the triangular ligament; and, as this part of the urethra is commonly the seat of permanent stricture, an irregular action of this muscle is supposed to have much to do with its formation; and if stricture existed only at this part, the inference would be a just one; but stricture often takes place at the orifice of the urethra, and for two inches backwards, to which parts no fibres of this muscle extend; and the membranous portion of the urethra, which is surrounded by a muscle acting as a sphincter, and whose description I have given at length, is supposed by most persons to be free from this disease. If, then, the part posterior to the accelerator is free from stricture, although more intimately and closely connected to and surrounded by a stronger muscle than the accelerator, when compared with the space it covers, whilst the very anterior part which has no muscle at all, is affected by stricture, I think it must be admitted, that the action of the accelerator muscle cannot be the cause of stricture in the intermediate part. In the horse, the accelerator muscle surrounds the whole of the urethra, anterior to the pubes, nearly up to its orifice, and its action is assisted by the two retractor muscles which lie upon it, but in man the accelerator does not continue along the under part of the urethra, to near its extremity. Now, if the horse had stricture at this part, and the man had not, then it might be fairly attributed to the action of this muscle, but as this is not the case, the undue action of the accelerator urinæ, or ejaculator seminis, as it is also called, can only be supposed to keep up and increase the mischief, when the parts within are inflamed or irritable, but it cannot give rise to it alone.

The whole anterior portion of the urethra, or that part in which stricture is usually situated, is surrounded by the corpus spongiosum, and it is to it that I am disposed to attribute the principal share in the formation of the worst kinds of permanent stricture, and the great difficulty which is experienced in

effecting a perfect or radical cure. When the membranous portion of the urethra passes through the triangular ligament it preserves its fibro-cellular exterior, and more particularly at the upper part to which the bulb of the corpus spongiosum is not applied; but when the corpus spongiosum does surround the urethra, this external fibrous cellular covering leaves the internal mucous membrane, and is attached to, and merges in the elastic structure of the internal layer of the erectile tissue of the spongy body, to which the mucous membrane is so intimately attached as to be separated only by scraping with considerable care, and thus destroying the shreds of attachment between them, which are in some places more strongly marked in the general cellular attachment than at others. At the part, where the urethra enters the glans, the erectile tissue is thinnest, the urethra is nearer the surface and is supposed to be wider. Some large follicular glands are situated at this part, which is called the fossa navicularis, and are prone to enlargement, terminating occasionally in the formation of fistulæ in the prepuce of a very troublesome nature, but it is not often the seat of stricture. Here are three dissections of these parts, illustrating what I have said. The thinness of the internal membrane and its attachments to the elastic internal layer of the spongy body are well shown in each. The manner in which the urethra enters the corpus spongiosum is also evident, and the highly vascular texture of the bulb and spongy body is also shown by injection from the internal pudic artery. It is nearly as red as the inside of the stomach in an infant. The whole corpus spongiosum, including the bulb, seems to be formed originally in two symmetrical halves, or parts, and to unite to form one body, much after the manner of the corpora cavernosa penis. In some of the dissections made by Mr. Taylor, the septum, in the centre of the bulb, is well shown, and may be traced along the corpus spongiosum; but these parts still require a closer investigation. The elasticity of the urethra when surrounded by the corpus spongiosum, is best shown by introducing a solid sound into it, and turning the point forcibly downwards, when it may be stretched to a considerable extent in every direction. This may be done in the living body without giving pain, with the exception of the orifice of the urethra which will yield but little. If the person should have an old narrow permanent stricture at the distance of three inches from the orifice the experiment is made most conclusively, for the urethra stretches at every part anterior to it with great ease, but when the solid sound reaches that point it can penetrate no further, the elasticity of the part is lost, the hardened obstacle formed by the stricture is distinctly felt from the outside, and by a little turning downwards of the sound, its point, carrying the urethra before it, can be felt through the external parts projecting below the obstacle. If a sound just large enough to

go through a stricture of this kind be passed, and the part be examined between the finger and thumb, the extent of the stricture may be easily ascertained by the hardness, which is quite peculiar and distinct from the feel of the part either before or behind it. If the instrument be withdrawn and the part be again examined the hardness is very perceptible, when compared with the soft elastic sensation communicated by the spongy body in its natural state. The hardness is sometimes like a cord, and occasionally when circumscribed, like a small hazel nut. In the erectile state this hardened part is not augmented in size, the spongy body is distended before and behind it, whilst it remains a stationary hard line, or spot, connecting the two distended parts together, and when the stricture is in an irritable state often giving pain. If this hard part be cut into, the corpus spongiosum seems to have lost its spongy appearance, its erectile texture has become consolidated, and resembles rather a solid substance than an elastic structure. This kind of disease is very apt to form when the urethra is ruptured, during the severity of what is termed a chordee. It yields to the distending power of the two erectile bodies, and the inflamed part which has lost its elasticity is torn; the tear extends into the spongy body itself, blood flows freely from the orifice of the urethra, and the cells of the corpus spongiosum around the rupture become loaded with it. Inflammation follows, and, without great care be taken in the treatment, a permanent stricture is the result. Old Heister used I believe to recommend that when a chordee was troublesome, and the part had an undue curvature, it should be cured like many other obstinate things by beating it straight, in which operation the urethra was usually ruptured, when the flow of blood relieved the symptoms for the time, to cause perhaps a more permanent evil.

When the mucous membrane is inflamed, and has lost part of its elasticity, it does not always yield as readily under distension as some of the interstitial parts of the corpus spongiosum, which when they give way, allow the blood to be effused in the strict sense of the word, and a soft swelling takes place, which is a sufficiently remarkable although not a very common accident. I have just now under my care a young gentleman, who has a soft swelling of this kind about two inches and a half from the orifice of the urethra, and which appeared suddenly. The urethra was inflamed at the time, but was not ruptured; a full sized bougie could and can be readily passed along it. It gradually altered its appearance, became less, and would I think have gone away altogether, had not another gonorrhoea supervened, which by adding new symptoms, has rather increased than diminished it, and without great care a stricture will possibly be the result. In a case which I treated many years ago in the York Hospital, the swelling situated in the same place was as

hard and as circumscribed as if a Barcelona nut had been inserted into the under part of the urethra. It was quite cartilaginous to the touch, and the man made his water almost by drops. I removed this disease by the repeated but careful application of the *argenti nitratum*, so that no signs of it remained externally, the hardness having gradually diminished until it went entirely away. The man, a soldier, was to have been discharged, but on leaning over his bed to fold up the blankets one morning, he fell forward dead. I opened him next day, and found his heart diseased. The urethra appeared quite sound, and to my great surprise nearly as much so at the part which had been affected as any other. I had a preparation made of it, and it is or ought to be in the museum at Chatham. Lest you should go away with the impression that a stricture of this kind may always be cured by caustic, I must mention to you the case of a gentleman who consulted me a short time afterwards. He had a similar swelling situated at the part where the scrotum joins the penis. I was delighted to have the case and felt assured of a similar termination, but no such thing took place; the swelling and hardness increased rather than diminished, and at last I was obliged to divide the part from without inwards to save his life, by giving free passage to his water. I have since had many other cases of a like nature, all of which have been treated and relieved with various degrees of success, but none so pre-eminently well as the first. You will ask me perhaps, why? I can only say, it is as difficult to answer you on this point, as it is to tell you why in some cases of almost impermeable stricture a permanent cure is effected by simple dilatation, whilst in others as nearly alike as possible, the relief obtained is only temporary. It depends on the various shades of distinction between diseases, and on the particular extent to which each peculiar structure is affected. Experience assisted by careful observation may enable us to select the best and least dangerous mode of treatment, but it has not as yet enabled us to mark all the distinctions and shades of difference between these diseases, which it is necessary we should know to arrive at a more perfect knowledge of their treatment.

In repudiating the opinions which have been entertained of a muscular structure of the membrane of the urethra being the cause of contraction in this part, you must not suppose from what I have said, that it is entirely attributable to the elastic structure of the corpus spongiosum. I have demonstrated to you, contrary to the received opinion of all modern surgeons, that stricture takes place at the neck of the bladder at the inner end of the urethra, to which part the corpus spongiosum does not reach by a considerable distance, it cannot therefore when in this situation, be attributed to it, and all that can be admitted is, that the corpus spongiosum con-

tributes largely towards rendering a contraction more permanent and more difficult of cure. I can flatter myself that I have told you why a stricture may be more obstinate, more permanent, and more difficult of cure, where the urethra is surrounded by the corpus spongiosum than where it is not so situated, but I cannot flatter myself that I have told you why those parts of the urethra which are called membranous and prostatic are free from this contraction or stricture, which is so common in every other part. If the membrane of the urethra at its vesical end, or the very commencement of the bladder itself, connected only with cellular structure, or a few muscular fibres, can in any cases however few, become hard and inelastic so as to form a bar or stricture, it is quite plain that the very membrane itself must possess some properties, the deprivation of which leads to the evil, but of which properties it is possible it might not be deprived by a cause exerting an influence of the same extent and degree when dissimilarly connected. For instance, low inflammation at the neck of the bladder may produce contraction and loss of elasticity there, when it cannot do so a few lines more forward where it is nearly surrounded by the prostate gland; and active inflammation as well as chronic may give rise to it in that part of the urethra which is surrounded by the corpus spongiosum, whilst it does not generally do so in the membranous part, which is enveloped only by a fibro-cellular and muscular structure. In this statement you will perceive I admit that the membranous part of the urethra does not usually originate a stricture, but I do not affirm that it is always free from that complaint, or that it is not communicated to its anterior part by continuity of structure and extension of disease.

The loss of the elasticity of these parts is to be accounted for, and my belief is, that it is caused by inflammation in all its various shades and stages, and in this I support the opinions of Sir C. Bell, Mr. Shaw, and others, against those of Sir E. Home, Mr. Wilson, and the host of authors who directly or indirectly take a different view of the question, and attribute the contraction to a wrong action of muscular fibres which have not been satisfactorily shown or proved to exist. The most remarkable fact on this point I have stated, viz. that in the membranous part of the urethra, which is now known to be surrounded by a very powerful compressor muscle, the advocates for muscular contraction admit that contraction does not take place, and if it does not take place there, it is and will be difficult to prove why it should occur from that cause any where else.

The urethra is scarcely sensible to its natural stimulus when in its normal state, but when it is affected by inflammation or irritation its sensibility is so greatly augmented and its sympathies are often so peculiarly developed as to excite intense anxiety and suffering. The appearance of the urethra when the canal is

slit open varies a little in colour; during life there can be no doubt of its being of a bright red, which arises from its great vascularity, a fact easily ascertained by separating the sides of the orifice; this redness gradually diminishes in intensity in the course of the urethra, and after death it disappears, and the inside of it is found more or less of a light yellowish colour, deepened or redder at those parts which in general possess most sensibility when in a state of irritation. Thus the bulbous and membranous portions, and particularly the bulbous, are of a reddish colour, whilst the prostatic part is of a pale yellow, yet that and the neck of the bladder, whose colour is equally pale, are often most acutely sensible.

The surface of the urethra in a state of health is lubricated by a secretion of mucus sufficient to defend it from the irritation of the urine, but not so abundant as to flow from the orifice, the edges of which are scarcely more than moist, unless some irritation greater than usual has taken place in the canal. It is secreted in all probability by the whole mucous surface, but particularly by the various lacunæ which are distributed throughout, and which seem to pervade especially the most sensible parts. Those situated in the fossa navicularis, about an inch from the orifice, are often the cause of much inconvenience, both from abscess and from increased secretion. The orifice of the urethra is not a round opening, but rather resembles a mere slit, from the edges being applied to, or in contact with each other, a state which is supposed to exist throughout when the parts are quiescent. When the erectile tissue is distended, the urethra is elongated, the sides are separated from each other, and the canal becomes more or less enlarged or round. It is only fully distended by a continued stream of urine.

The urethra thus formed is a tolerably strong canal, and not liable to be perforated by instruments introduced into it, when they are used with dexterity and moderation. Like every other part of the body it is liable to abuse, and there is nothing which may not be done to it by ignorant and violent men. The membranous portion has usually been supposed to be most easily and most frequently torn; I am convinced, however, from repeated dissections, that this is not the case, that false passages usually begin in the bulbous portion, and pass by the side or under the membranous part towards or into the bladder, or they begin at the termination of the membranous part, and pass through the prostate. Mr. Powell, of Great Coram-street, when surgeon to St. Clement's workhouse, was so good as to give me a prostate which had five openings through it from the urethra into the bladder, made at different times by the catheter, and which gave little comparative uneasiness, the person dying at last of an acute disease, I believe of the chest.

ANATOMICAL NOTES.

DISCOVERY OF THE TRUE DISTRIBUTION OF THE OBTURATOR NERVE.

BY ALEX. THOMSON, M.B., OF ST. JOHN'S CAMB.

Most friendly but sceptical reader, be kind enough to take once more the scalpel in hand, and cut down to the inter-muscular interval, between the adductor brevis and magnus muscles, and there, among other nervous twigs coming from the posterior lamina of the obturator nerve, you will find one that plunges apparently into the adductor magnus, somewhat lower down than the others, but which, if you believe it possible for such great men as Meckel and Velpau to be deceived, and thence take the trouble of following, you will trace, passing between these muscles into the adductor-vastal sheath of the femoral vessels, to penetrate into the true sheath of the vessels, creep between the popliteal vein and artery into the popliteal space, and accompany these vessels thence in their branchings, as far at least as to the line where the middle meets the inferior third of the leg. This will no doubt stagger you with respect to the dogmata of these gentlemen, but be kind enough to examine this erratic branch, and you will find that great names are sometimes too easily obtained, and pass under their shelter much that is not well done. But you will not be displeased with me for sending you once more to school, when you shall find that this filament furnishes a twig to all the perforating arteries, to the articular branches of the knee-joint, to all the secondary twigs of the popliteal and posterior tibial and fibular arteries, but also that it sends numerous filaments through the reflected tendon of the serous membranous muscle to perforate the posterior ligament of the knee-joint, and be distributed in a fine net work over the unpolished surface of the synovial membrane. But Meckel has already pointed out the twigs passing into the round ligament of the hip-joint by entering through the space behind the anterior crucial ligament of the cotyloid cavity; yet, in addition to this, you will find one insinuating itself through the pelvic fascia into the iliac fossa, and passing forwards to arrive at the iliac fossal-cursa mucoea of the iliac and psoas muscles, give it some twigs, and then pass on to plunge into the anterior part of the capsular ligament of the hip-joint, and be lost by innumerable anastomoses on the synovial membrane, thus establishing an anatomical cause for the great sympathies existing between the hip and the knee-joint. If you detest minute anatomy be kind enough to go no further; if, however, your curiosity is excited you will peruse the following details, which will, I hope, amply repay your trouble.

Obturator Nerve. Its direct connexion with the sympathetic of the lumbar region.

18th Subject. Male, right side.—The ob-

turator nerve in this case arose from the anterior roots of the second, third, and fourth lumbar nerves, and immediately at the point of junction of its third root, that is opposite to the middle of the posterior margin of the side of the body of the last lumbar vertebra, received a branch from the sympathetic, about one-third of a line in diameter, which from thence ascended obliquely upwards, forwards, and slightly inwards; winding round the groove made by the last origin of the psoas magnus, coming in this case from the quarto-quintal lumbar articulation, till it arrived at the anterior margin of the muscle; having arrived there, crossed the articulation, then ascended upwards along the interior edge of the vertebral origins of the psoas muscle, and terminated by being lost in the inferior extremity of a ganglion, lying on the secundo-tertiar lumbar articulation, having sent some filaments to the ganglion, lying in front of the tertio-quartal lumbar articulation, and also to that lying over the quinto-sexual lumbar articulation.

This was seen and verified by M. Daniel Roy, surgeon, August 10th, 1833.

Obturator Nerve. Its branches to the anterior part of the capsule of the hip-joint.

2nd Subject. Female.—This nerve in its pelvic course ran above the artery, which in its turn lay above the vein, notwithstanding the arrangement given by Cloquet (which see, § 1743).

The nerve opposite to the sacro-iliac symphysis gave off a branch, a quarter of its own magnitude, running along the inner margin of the iliacus-internus muscle exteriorly to the iliac fascia, upon the margin of the upper strait of the small pelvis, as far as the posterior extremity of the ileo-pectineal eminence, where it passed forwards in contact with the eminence, and in the groove made by its surface, and the attachment to the same of the psoas parvus tendon, so that here it lies between the psoas magnus and parvus; after passing forwards as far as the anterior margin of the ileo-pectineal eminence, it divided into two twigs, both of which descended behind the psoas magnus and iliacus, to be lost upon the capsular ligament of the hip-joint. Right side; left not examined. May 5th, 1833.

The same arrangement of parts and distribution of twigs were found in a female who died of venereal caries of the palate and sphenoid and maxillary bones, in the venereal hospital, on May 6th, 1833.

Origin.—In the fourth and fifth subjects, both female, it arose by roots, equally large, from the second, third, and fourth lumbar nerves, each root crossing vertically before the origin of the nerve below it, and in close adhesion with that origin, and successively shorter from above downwards. May 11th, 1833.

(To be continued in our next.)

CONTINUATION OF M. ALIBERT ON THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

Late Senior Surgeon to the Royal Metropolitan Infirmary for Children, &c.

ARTICLE III.

Of the external Causes thought likely to favour the development of the Teignes.

GROSS and indigestible food, particularly that abounding in albuminous principles, ranks among these. It has been likewise attributed to the filthiness in which some children are brought up; these causes may undoubtedly contribute to it, as it is most commonly the sad appendage of poor people. The favous particularly attacks individuals who have lived in dirty and damp places; the parts of Paris inhabited by the poor abound with it; but this affection sometimes attacks children of rich parents, although they are more liable to the granulated or mucous scald. Is it through contagion that the disease is propagated in so rapid a manner among the children of the poor? Is it through the custom they have of using the same comb for their hair? Some observations appear to prove this; the greater frequency of scald heads in town than country aids this assertion; however, I must say the dangers of this form of communication have been greatly exaggerated. M. Gallot has proved by four cases that if the scald head is contagious, it is much less so than is thought, and that it wants, at least, preparatory causes to facilitate its transmission from one individual to another. He mentions in his thesis at the Ecole de Médecine, Paris, an officier de Santé who vainly tried to give this disease to two little scrofulous girls, in the belief that their bodies contained the seeds of the disease, and it was important to make it come out on their skins; it was vainly that for eight days he put every evening on their heads a linen dipped in the matter of the disease. This

surgeon, notwithstanding, succeeded afterwards in communicating the favous form to another child, six years and half old, by the repeated application of a cataplasm so much impregnated with teignous virus that it emitted a foetid odour like that of a cat's urine; but M. Gallot cites two further cases where the infection has not been effected, notwithstanding the most favourable circumstances. Particular circumstances which I have witnessed appear to me equally to confirm the opinion of the difficulty there is in propagating the disease when it is desirable. I have seen a child brought up at school who has never communicated the granulated form, with which she was afflicted, though they neglected separating her from her companions, with whom she continually played. Jeanne Magdelaine Duval, aged 13, who came to the Hospital St. Louis for advice, slept constantly with her sister for six months without communicating the favous with which she had been afflicted from infancy. I could give a number of similar instances. It is evident that the degrees of power of infection are not yet clearly defined; this problematical question requires new inquiries. An infinite number of causes have been assigned with reason to the cutaneous affections in question, in general every thing which increases the activity of the circulation determines to the head. Among these causes may be reckoned trouble, anger, and other passions, to which nurses imprudently abandon themselves. There was at the Hospital St. Louis, Lucie Dugard, aged twenty-two months, born of a mother who was continually in violent passions. This child having been suckled by her in the midst of these choleric fits, was attacked with the mucous teigne, which occupied the forehead and face, and emitted a yellowish and viscous humour. This disease decreased remarkably when the mother was calm, and especially when sober, for we learn that she was always getting intoxicated, and was besides of immoral habits.

ARTICLE IV.

Of the Particular Seats of the different kinds of Teigne.

THE seat of the teignes is a very interesting question to pathologists. Several authors have established its primitive origin in the bulbs of the hair, but no positive conclusion has been arrived at; the alopecia, or baldness, has been vainly alleged as an unexceptionable proof of the correctness of this assertion, for, besides its not being constant, and being only observed in scald heads at advanced stages, it arises in other diseases intirely foreign to the scalp, besides the favous teigne attacks parts entirely devoid of hair, as the back of the shoulders, the loins, thighs, &c. The forehead, face, ears, &c., are liable to the mucous form; it is, therefore, to be presumed, that some change in the reticular tissue, or rete mucosum, may prove the true origin of these diseases. The hair can, in general, only thrive when this structure is duly discharging the functions belonging to it; it must consequently decay when the necessary moisture is wanting for its nutrition. Is it not thus that plants cease to vegetate and grow on a barren and unkind soil?

ARTICLE V.

Of the Results of Autopsy in the different kinds of Teigne.

I HAVE not neglected this inquiry, though the accidents, which follow the invasion of scald heads, rarely occasion death; but it is sometimes complicated with other diseases, much more dangerous, which afford more frequent occasions of anatomical examination.

CASE 1. — *Of Examination post mortem.*—The individual in question died under our observation at the Hospital St. Louis, in consequence of the favous form, which attacked almost the whole of his body. He was a beggar, 13 years of age, was without an asylum, and often slept in the streets of Paris; he was so emaciated he fell a victim to it even

before we could question him respecting the relative accounts of the origin and progress of the disease. The anatomical observation of the body gave the following results: all the scalp was covered with a cap, formed of favous crusts, some of which were yellow, regularly in the form of a cap, and others white and broken, offering only a mass of scabs without any determined form; the skin had many longitudinal fissures, excoriated and daubed with a bloody concretion, and it was deprived of epidermis; the rete mucosum, the cutis, and the subcutaneous cellular structure participated in the alteration; the parietal, occipital, and frontal bones were stripped, and had a reddish aspect; the divided skin of the neck showed a string of hardened glands. On the shoulders, loins, and external parts of the thighs were large plates of favous scabs, some of which, in falling off, left the skin stained, of a dark violet colour; others, which were very adherent, were excavated in the middle, like those in the scalp. There was nothing particular in the brain. The chest and abdomen were equally sound. Along the mesentery was a series of small scirrhous and white concretions; the liver, spleen, and intestinal canal were not damaged.

(To be continued.)

Reviews.

Signs of Pregnancy and Delivery.

By W. F. MONTGOMERY, M.D.,
Prof. of Midwifery to the School
of Physic in Dublin. Lond. 1833.
Royal 8vo. pp. 45.

From the "Cyclopædia of Practical Medicine."

Observations on Obstetric Auscultation, with an Analysis of the Evidences of Pregnancy, and an Inquiry into the Proofs of the Life and Death of the Fœtus in Utero.
By EVORY KENNEDY, M.D., Lecturer on Midwifery and Diseases of Women and Children at the Richmond Hospital School, and late

H H

Assistant to the Dublin Lying-in Hospital. *With an Appendix containing Legal Notes.* By JOHN SMITH, Esq., Barrister at Law. 12mo. pp. 268. Four Plates.

OUR Irish brethren have, within a few years, thrown off that lethargy which so long oppressed them, and are now among the most prominent supporters of the medical literature of these kingdoms. The many works which have issued of late from the Dublin press are some of the most valuable contributions to the annals of medicine, and have proved what many short-sighted persons were led to doubt, that there are clever and able members of the profession in Ireland as well as in other countries—that something good might yet come from Nazareth. If proof were required of us in support of this position, we should adduce the Dublin Hospital Reports and Transactions, the various productions on Fever, the works of Carmichael, Harrison, Hargreaves, and Wallace, the Dublin Pharmacopœia, the Dublin Journal of Medical Science, and though last not least, the lectures of Graves, Stokes, and Mac Adam, in this Journal. The works now before us are justly entitled to be added to our list, for both are ably executed, and well deserving of praise. The subjects of which they treat are of considerable importance in forensic and obstetric practice, and are more fully considered than in any works with which we are acquainted. Both authors discuss the same points, but Dr. Kennedy extends his observations to obstetric auscultation in dystocia or difficult parturitions. We regret that our space will not allow us to give long extracts; we must therefore confine ourselves to the conclusions arrived at by both writers.

Professor Montgomery commences his subject by referring to its relations with criminal and civil law, the importance of determining the existence or absence of pregnancy, legitimacy, succession to property, concealed and

feigned pregnancy, the inquiry concerning gravidity in stay of execution, and the inquiry, at the instance of the heir presumptive, on a writ *de ventre inspiciendo*. The learned author gives a case, in which a pregnant woman was executed in consequence of the ignorance of medical witnesses. He then proceeds to examine most minutely all the signs of pregnancy. After a general history of the usual signs, we have next a comment upon each of them.

Suppression of the Menses.—This generally occurs; but numerous authorities are cited to prove that menstruation may recur once and oftener after conception, and also that pregnancy has happened before menstruation has been established. *Nausea and vomiting—Salivation and Affections of the Mammaræ*.—There is nothing new under these heads. *The Areola*.—In the section relating to this sign, great importance is very judiciously attached to the change of colour in the areola, which succeeds conception in most cases; and this commences at the end of the second month, according to our author. It varies in hue according to the complexion of individuals; its extent is from one to three inches in circumference at the end of utero-gestation: but pregnancy may exist without it. Wherever it appears it is a strong presumptive proof of an existing or former pregnancy. Several instructive cases are detailed in support of this conclusion. We pass over the section *Milk in the Breasts*, as this sign is most equivocal. *Quickening and the Motions of the Fœtus*.—Under this head the experienced Professor descants upon the absurdity, injustice, and immorality of the law, which considers the embryo inanimate before the fourth month; as all physiologists and medical practitioners are unanimous in the opinion, that the fœtus is alive from the first moment of its existence. The law is most inconsistent and contradictory, which enacts, that the embryo is entitled to an estate *en ventre sa mère*,

from the moment of conception; and yet may be hanged four months afterwards for the crime of the mother. (See Paris and Fonblanque, vol. iii. p. 141.) Cases are adduced, in which the parent never perceived quickening or the motion of the foetus, though it was born alive; and one remarkable case is detailed, in which the woman did not feel the motion of the foetus, though clearly felt by the author, Dr. Marsh, and Mr. Cusack. Again; a medical practitioner said he had repeatedly recognised the infantile movements, though the author found that there was no pregnancy. In cases of pregnancy complicated with ascites, ovarian dropsy, or large tumours, it may be difficult, if not quite impossible, to detect the movement of the foetus. A case in point is detailed, in which auscultation was useless, though the foetus was living. According to the Professor's experience, quickening usually occurs two or three weeks before the fourth month of utero-gestation, and sometimes much later. Every obstetrician knows that the same woman will quicken at different periods during successive pregnancies; and examples are recorded which prove that quickening, or the motion of the infant, may not be felt until the moment of parturition, and the infant be born alive and vigorous.

The next sections are, *Size of the Abdomen and state of the Umbilicus*—*State of the Uterus*—*Ballottement*—*and Application of Auscultation*.—All these are treated ably. The author is of opinion, that the placental murmur cannot be heard sooner than the fourth month, at which time the fundus uteri ascends above the pelvis. Velpeau arrives at the same conclusion. Others have supposed they heard this sound (*bruit de souffle*, bellows sound,) so early as the tenth week.

The next subjects considered are, *Substances expelled from the Uterus*—*an early Ovum*—*Moles*—*Hydatids*—*Membranes expelled in Dysmenorrhœa*—*Accidental circumstances*—*Expression of the Countenance*—*Signs*

afforded by the Blood, Urine, Pulse—*Age of the Individual*.—There are some curious facts in the last section. The author holds that conception before the age of fourteen is very rare, but he cites some authors, who alleged that it occurred at the ninth year in Abyssinia and Bengal. He likewise quotes cases of pregnancy from the fiftieth to the sixty-third year. Professor Capuron remarks, as to the last case, that it was generally believed in Paris. In May last a case was decided in the English Court of Chancery, and an immense property taken from the heir, because no medical practitioner in London, at least none of those examined, had ever attended a woman in labour at her sixtieth year. The Editor showed the incorrectness of this conclusion, in vol. iii. p. 687, of this Journal.

The next section of interest is entitled *Conception without the Knowledge of the Woman*.—Medical jurists agree, that conception may happen while the woman is in a state of hysteria, under the influence of narcotics, during asphyxia, drunkenness, or sound sleep, and consequently without being conscious of it. A woman may likewise be delivered in any of these conditions. Two cases are detailed, in which a girl and a servant woman were impregnated during profound sleep; and when called on by the magistrates to swear to the fathers of their children could not do so. The mystery was cleared up by the respective fathers confessing the facts.

The remarks on the presence or absence of the hymen, contain conclusions universally received, that the hymen is not a proof of virginity.

The learned professor writes a long section on the *Examination of the Uterus and its Appendages*, and after citing all the physiologists who have written on the corpus luteum, and described the corpora lutea of various animals, specimens of which are in his museum, he arrives at the following conclusions, which distinguish the appearances so called before and after impregnation. The corpora

lutea in virgins differ from those of women who have borne children in the following particulars:—

"1. There is no prominence or enlargement of the ovary over them; 2. the external cicatrix is wanting; 3. there are often several of them in both ovaries, especially in patients who have died of tubercular diseases; 4. they are not vascular and cannot be injected; 5. their texture is sometimes so infirm that they seem to consist merely of the remains of a coagulum, and at others fibro-cellular, like the structure of the ovary, but in no instance were they soft, rich, or of glandular appearance, or as Hunter described them, 'tender and friable like glandular flesh'; 6. they have neither the central cavity nor the radiated cicatrix which results from its closure."

The remainder of the essay is on the *Signs of Delivery*, and is as well executed as it possibly could be. The whole production evinces deep research, great experience, and sound judgment. We feel convinced that had it been published as an original essay, it would have extensive circulation; and it is decidedly one of the very best contributions to the work whose pages it enriches.

Dr. Kennedy has offered the profession an admirable work on the same subject, with much additional information on topics untouched by his contemporary. He adduces a host of authorities and numerous cases which had fallen under his observation, many of which were seen by others, in proof of the value of auscultation in enabling us to detect pregnancy so early as the tenth, eleventh, or twelfth week. According to his experience, which is very extensive, he never heard in a single case the *souffle*, or bellows-sound, with the ear, but in which he did as readily with the stethoscope. He does not agree with Siebold and Fodera, that the ear is preferable. He says it may be applied in cases of irritable nervous women, and attaches much importance to the application of the cheek also. In making this kind of examination, he places the patient on her back with a sheet thrown over. His conclusions on obstetric auscultation are extremely valuable, and in our opinion, perfectly satisfactory.

"As the first indication of pregnancy afforded by auscultation is the *souffle*, we shall commence with the consideration of that phenomenon.

If we examine, either with the naked ear or the stethoscope, the abdomen of the pregnant woman, we shall (provided the pregnancy be sufficiently advanced) observe a peculiar blowing or hissing sound. This sound is to be met with in almost every case, and is observed at different parts of the uterine tumour. It does not always exhibit exactly the same characters, yet these are sufficiently striking to render it recognisable in almost every case. It assumes the different varieties which Laennec describes under the term *bellows' sound*; namely, the bellows' sound, properly so called, likened by that author to the continuous murmur, similar to that of the sea, familiarly exemplified by the application of a large shell to the ear; the rasping or sawing sound, which is occasionally found so exactly imitated as to lead the listener to imagine an artisan at work quite close to him; and the musical or hissing sound, so well described by the same author. A sound, resembling the cooing of a dove, is sometimes observable, but this is comparatively rare. A more frequent peculiarity, to be noticed, is a strange drone resembling that of a bagpipe accompanying the sound, but yet without interfering with it. The most constant form we meet with, however, is a combination of the bellows' or sawing with the hissing sound, commencing with one of the former, and terminating with the latter; and this is in general so protracted, that the last *souffle* is audible when the subsequent one commences.

"These sounds are, from the distension of the uterus, and consequent facility of examination, easily detected in advanced pregnancy; and although not so loud or sonorous in the earlier stages, yet to the practised ear they become equally distinct. None of the above mentioned varieties are peculiar to particular stages of pregnancy, being detected indifferently in them all. The extent of surface over which the sound is observable, varies much according to circumstances; in some it is confined to a small circumscribed spot, in others it is audible over a greater surface, perhaps two or three inches square; and in a few it is to be met with over the greater part of the uterine tumour, although there is in many cases one spot in particular, perhaps not larger than the end of the instrument, where the sound is vastly more distinct and sonorous than elsewhere. The *souffle* is most frequently found in the lateral and inferior parts of the uterus, but it may have its seat in any part of it; and it must be added, that cases will occur, although, if proper precautions be had recourse to, very rarely, where we shall not be able to detect it. The cause producing the sounds in question requires explanation, with a view to which, we must briefly inquire into the nature of the vascular structure and circulation of the uterus."—pp. 64—66.

Dr. Kennedy enters into a long explanation of the causes of the placental murmur, which we omit, as of no practical importance.

The application of auscultation in determining the life or death of the foetus in utero, in dystocia parturitions, enables us to arrive at a positive certainty on this important question, and affords the practical obstetrician that information so long and so anxiously desired. Though the author before us lays no claim to originality in directing the attention of the profession to the value of auscultation in obstetric medicine, for he candidly acknowledges that the merit is due to Moir of Geneva, and Kergaradee, nevertheless he is entitled to great praise for having carefully established, beyond the possibility of doubt, what his predecessors had not done; that a certain diagnosis may be determined in doubtful cases of utero-gestation, from the tenth week after conception to the period of parturition, and in the numerous distressing cases, in which the practical obstetrician was to be guided in his operations by the life or death of a fellow being.

We consider this work one of extreme value, both on account of the novel information it contains, and the numerous interesting and embarrassing cases it elucidates and simplifies.

A Manual of Experiments, illustrative of Chemical Science, systematically arranged, with the Theory of Definite Proportions, Application of Tests for the Detection of Poison, Examinations of Mineral Waters, and a Vocabulary of Technical Terms. By JOHN MURRAY, F.S.A. F.L.S., &c. 12mo. pp. 109. Third Edition.

THIS manual is what it professes to be, and is an exceedingly useful text book for those commencing the study, or engaged in the practice, of chemistry. It cannot supersede the necessity of possessing the elementary and systematic works on the delight-

ful science of which it treats, but it is a safe guide for junior students.

Illustrations of Vegetable Physiology practically applied to the Cultivation of the Garden, the Field, and the Forest. By JAMES MAIN, A.L.S. 12mo.

THIS production is interesting to those engaged in horticulture, agriculture, botany, and an interesting portion of natural history. Vegetable physiology is an amusing study, and has thrown much light on the economy of the animal kingdom. This work will be perused with advantage by those interested in the pursuits to which it principally refers.

A Compendious History of Small Pox. By H. GEORGE, Surgeon.

THE history of small pox affords nothing very new for an author to dwell upon, or for a reviewer to notice, and we therefore regret that Mr. George should have filled the larger portion of his work with it. Although condemning the practice of others, he does not, to use his own words, feel himself called upon to recommend any specific remedies in the disease. The local treatment employed by him being the only one that wears at all the appearance of novelty, we shall transcribe it in his own words; he was led to employ it by reasoning from analogy of its utility in those cases of burn where the cutis is much abraded.

"The treatment consists in covering the body as completely as possible with an absorbent powder, (I have generally used the calamine); the advantages which follow the use of this dressing in the early stage of this disease, are, to moderate the violence of the local inflammations, and to prevent the painful tumefaction of the common integuments. After the calamine has been applied some hours, a very sensible difference is to be observed in the appearance of the parts so covered; the areola of each pustule being much less distinctly marked. It is not unreasonable to suppose, that even at this moment some advantage is gained by the application; the quantity of pus secreted may by this circumstance be diminished, and a great saving made

of the powers of the constitution ; but it is in the advanced stages of this disease that the greatest benefit is derived from this method of local treatment. It is at this time that we have it in our power not only greatly to circumscribe the field of suppuration, but to heal, on destroying the cuticle, by the process recommended, every pustule on the body, almost in the space of a few hours. To accomplish this is indeed a painful task. By the same process, those extensive portions of exposed cutis may be rapidly healed; exclude them also from communication with the atmosphere, and they cease to be sources of irritation. I have seen patches of exposed cutis, six or eight inches in diameter, at the end of two or three days, by this treatment, no longer occasioning disturbance.—pp. 71—74.

“The advantages attendant on this mode of local treatment are,

“1st. It entirely prevents the seaming or scarring of the skin.

“2nd. If it does not altogether prevent the pitting, it renders it comparatively trifling.

“3rd. It rescues the patient from those sources of danger, to which, from the eighth day, he is exposed; the consequences of the powers of the system being in a great degree exhausted.”—p. 83.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, November 2, 1833.

DR. GREGORY, President, in the Chair.

Medical Reform—Bad and good effects of Iodine in various Diseases—White Swelling on the Knee and Ankle-joints—Scirrhus Mammæ et Uteri—Ascitic and Ovarian Dropsy—Chlorosis—Hydrocephalus.

AFTER the minutes of the last meeting were read and confirmed, some other private business was transacted.

Dr. Gregory then expressed his warmest thanks to the Society for the honour they had done him in re-electing him their President, and pledged himself to discharge his duties impartially, while he felt satisfied that the Society would co-operate with him in enforcing the laws.

Dr. Somerville then gave notice, that on this night two weeks he would, with the sanction of the Society, introduce the subject of Medical Reform. He said that at present “we

belong to no medical corporation, and had no other place to consider our grievances than in this Society.” He should be happy to receive the suggestions of any of its members on the resolutions he intended to propose, and to modify the plan in any way that might be determined upon after due consideration.

Mr. Pettigrew observed, that agreeably to the laws of the Society, it would be necessary to reduce the proposal of Dr. S. to writing.

Mr. Hunt considered the subject of great importance, and that it was essential to the profession, that all its ranks should fight under one banner.

Mr. Holt felt happy that the subject had been proposed; and as he had communicated with Lord Althorp on medical reform, he should be happy to communicate his lordship’s opinion.

The President then announced that the time for medical discussion had arrived.

Dr. Roscoe wished to inquire of the Society, whether any of its members had observed symptoms of incipient amaurosis during the use of iodine. He had a patient labouring under diabetes, whose vision became impaired while using iodine, and he had heard of a lady in the country who suffered in like manner.

Mr. Greenwood observed, that iodine was extremely beneficial in various enlargements, but he had not seen the effects noticed by Dr. Roscoe.

Dr. Bradley said, that in Savoy, where goitre was common, and iodine extensively used for its removal, amaurosis was a frequent consequence.

Mr. Hunt remarked, that iodine was a powerful remedy, but one which required great caution in its use. In cases in which the brain was supposed to be indurated to some extent, and the diagnosis of such cases was extremely difficult, the remedy might do great mischief if an erroneous view was taken of the disease. It often caused constitutional disturbance when used externally, excited vascular action in the part to which it was ap-

plled, and deranged the digestive organs in many instances. The young practitioner should therefore be cautious in its employment.

Dr. Copland stated, that he had used iodine since 1820, (when he brought a quantity of it from France,) in visceral enlargements, all forms of scrofula, in dropsies, in chlorosis, and in bronchocele. He considered it a most valuable remedy; but a great error prevailed regarding its dose and employment. He was in the habit of recommending the iodureted solution, consisting of iodine, hydriodate of potass, and water. He had known several cases in which the remedy was prescribed by others without benefit, because it was ordered in too large doses; and yet it effected a cure in his hands. He related many cases in proof of this statement, in one of which it caused dysentery.

Dr. Ryan said, that in consequence of being connected with a public institution, St. John's Hospital, and of being a strong advocate in favour of the great efficacy of iodine, he had employed it in a large number of cases. He fully agreed with Dr. Copland in all he had said concerning it; and felt convinced that the reason it had failed or produced bad effects, was because it was generally given in improper doses or in an objectionable form. He had employed it successfully in all the diseases mentioned by Dr. Copland, and in many other diseases not yet noticed this evening by the Society. He had given the aqueous solution of it to infants at the age of two years and a half, in mesenteric and rachitic disease, and from that age upwards, but he had never observed the bad effects ascribed to it by Mr. Hunt. He had found it effectual in white swelling of the knee and ankle-joints, and if Dr. Negri, his worthy colleague, were present, he would corroborate this statement. He, Dr. R., had tried it in the case of a lady, who was declared by two eminent practitioners in the country, and by others in town, to labour under scirrhus of the breast, for

which amputation or excision was proposed, but the iodureted combinations effected a cure. He had tried it in a case of scirrhus uteri, for which his advice was requested by Mr. Matthews, of Hunter-street, Brunswick-square, and with complete success, though he agreed with Mr. M. at first, that the case was hopeless. The lady had all the symptoms of malignant scirrhus, recovered, became pregnant, and since married a second husband. He had employed it in ovarian dropsy with perfect success; and he knew a case of ascites with liver disease, in which fourteen quarts of fluid were extracted, the abdomen in a few days became as large as before tapping, and under these circumstances the hydriodate of potass alone, in doses of from five to fifteen grains twice a-day, was given, and an ointment of iodine, hydriodate of potass, and axunge rubbed over the liver. The result was, that a perfect cure was effected, though the patient had been tapped.

Mr. Costello agreed with Mr. Hunt as to the constitutional derangements caused by iodine, and was of opinion, that when the tissue was diseased iodine was of no use. He doubted the cases of scirrhus breast and uterus, for scirrhus was supposed to exist when there was merely engorgement. He had employed iodine in diseases of the prostate gland with benefit.

Dr. Ryan rejoined, that the ablest medical men in France—Magendie, Dumeril, and Serres—were deputed by the Academy of Medicine to observe the patients under M. Lugol, and they assured the Academy that they had never seen any bad effect from iodine, when used as recommended by Lugol, that is, chemically and scientifically. Mr. Costello's assertion might be very satisfactory to some persons, but he (Dr. Ryan) would prefer the evidence of ocular demonstration. The cases he had related had been seen by others. He (Dr. R.) might be mistaken, but the testimony of others was entitled to as much credence as Mr. Costello's.

Dr. Negri remarked, that he considered iodine a most powerful and valuable remedy. He was really astonished at the result of two of the cases mentioned by Dr. Ryan—white swelling of the knee and ankle joints, in which the most surprising good effects were produced, and a cure effected, though amputation had been proposed before the use of the remedy.

Dr. Somerville observed, that he had witnessed the levée at the house of Dr. Coindet, in which that learned physician foretold, with astonishing accuracy, all cases he could cure, and all in which he would fail. Dr. S. was decidedly in favour of iodine.

Mr. Quain stated, that he had most experience with the effects of iodine and its preparations in scrofulous ulcers. In some cases it disagreed at first, and was obliged to be abandoned. When the digestive functions were attended to, and the remedy again employed, it produced rapid cicatrization. He preferred the aqueous solution, and other preparations, mentioned by Dr. Copland, which were those of M. Lugol.

Mr. Stodart related cases in which he had seen a drachm of the tincture of iodine exhibited three times a-day without any bad effect. He employed the combinations of the remedy mentioned this evening in his own practice, and had never witnessed any constitutional disturbance.

Dr. Copland rose to sum up, in conclusion, the remarks that had been made this evening. He corroborated Dr. Ryan's statements from his own experience. He dissented from the conclusions of Mr. Costello, especially as to the inutility of iodine when there was change of structure in a part. In scrofula of the neck there was a deposition of fluid, semifluid, or curdy matter, and yet iodine removed the disease. It was useful in chlorosis, and excited the genital organs. He had seen a scirrhus breast cured by iodine; but he was aware it was extremely difficult to decide when such disease existed. The usual symptoms were present in the case to which he

alluded. He also tried it in chronic hydrocephalus, but he would reserve the results for some future time. He had lately recommended Dr. Malins, of Liverpool, a gentleman known by his literary attainments, to employ the hydriodate of potass in hydrocephalus. He would state, in conclusion, that he had found iodine, in small doses, a valuable tonic, and had seen patients who had fallen into flesh after its employment. He had used the remedy in cases of diseased prostate with and without success.

Mr. Costello, Mr. Hunt, and Mr. Greenwood, mentioned the difficulty of determining the existence of malignant scirrhus of the uterus, even by the ablest practitioners. It was well known, that partial excision of the uterus had been frequently performed when no scirrhus existed.

Dr. Gregory said, that as Chairman, he declined to take any part in the discussion. He would now remark, as the discussion had closed, that he was officially appointed to visit the Royal Sea Bathing Infirmary at Ramsgate. In that Institution there were 250 patients, 150 of whom were treated by iodine, or its combinations. No bad results ensued; there was no constitutional disturbance as described by Mr. Hunt. In some cases there was severe local inflammation excited. It was worthy of remark, that Mr. Chalk, the medical superintendent, had told him that the iodureted ointment often produced the worst effects. A better formula was the solution, composed of three grains of iodine, six, eight, or twelve of hydriodate of potass, and ten or twelve ounces of warm water, used as a fomentation.

The Society then adjourned.

NOBLE LEGACY.—Mrs. Ann Wignall, of Kensington, has bequeathed £4000, three per cent. consols, to the Norfolk and Norwich Hospital, after the death of Mr. Marchant Tubb, aged about 68.

MEDICAL SOCIETY OF LONDON.

Monday, November 4, 1833.

WILLIAM KINGDON, Esq., President,
in the Chair.

THIS was a special general meeting of the Society, for the purpose of taking into consideration the conduct of the medical officers of the General Dispensary, Aldersgate-street. The meeting was numerous and most respectably attended, and several non-professional gentlemen were present.

A gentleman inquired whether visitors would be allowed to take any part in the proceedings of the evening.

The President replied that members of the profession only were entitled to that privilege.

Dr. Waller then rose to propose the first resolution. He regretted that this society, which was the oldest in London, had not come forward at an earlier period to express its opinion on the important principle on which the late medical officers of the General Dispensary, Aldersgate-street, had so nobly acted. He ably explained the evil effects of the law adopted by the committee, as it would give the office, not to the candidate who had most brains, but to him who had most sovereigns. He deemed it unnecessary to prove that this would be most injurious to the interests of the charity, of the poor dependent upon it, and of the dignity of the medical profession. He then forcibly pointed out that the new laws destroyed all competition among medical gentlemen, and concluded a very able speech by proposing the first resolution, which will be found at the end of this report.

Dr. Williams seconded the resolution, of which he highly approved, which was carried unanimously.

Dr. Uwins then addressed the meeting on the claims which the late medical officers had, not only to the thanks of the profession, but the public. He eloquently eulogised the scientific attainments and contributions made by the eminent gentlemen whose philanthropy led them to sacrifice self-interest to public good.

Mr. Dendy, in classic and eloquent language, seconded this resolution.

Dr. Spearman now moved the third resolution—of thanks to His Royal Highness the Duke of Sussex, and pronounced a just eulogium on that illustrious personage, for his readiness at all times to promote the interests of science and the cause of humanity, and in particular for his patronage and support of the late medical officers of the Aldersgate-street Dispensary in their praiseworthy conduct.

Mr. Drysdale felt sincere pleasure in seconding this resolution.

Dr. Ryan proposed the fourth resolution. This related to the dignity of the profession, and as some persons denied this, especially the committee whose conduct was under consideration, he should, though it was perfectly unnecessary, inform such individuals, some of whom were present, upon this subject. The moral statutes of the profession bound each of its members to support its dignity, and to do all in their power for the promotion of medical science, and the relief of their fellow-creatures when suffering from disease. The dignity or utility of the medical profession was not supported by those who advocated the absurd and erroneous principle, that the youngest of its members were as competent to treat disease, or prescribe for the sick poor, as the most learned and experienced. This was the error into which the Aldersgate-street committee had fallen, and, unfortunately, it was acted on by the subscribers of most dispensaries. He gave the committee due credit for preventing the corrupt practice of making proxy or pocket votes, and for preventing premature canvassing, but they completely nullified these salutary laws, by enabling a candidate to make as many votes as he pleased seven days before the day of election. The voice of the profession was against this law, and in favour of the opposition to it by the late medical officers, and those who acted against the feeling of their brethren would learn very soon that they were in error.

Dr. James Johnson felt great pleasure in seconding it; and, in an able and comprehensive speech, depicted corruption in all elections, from the crown to the parish beadle; the professions of law, physic, and divinity; the army, navy, &c. included. In his opinion the only rational mode of electing medical officers to hospitals, infirmaries, and dispensaries, would be to have the whole body of physicians vote for physicians, surgeons for surgeons, and apothecaries for apothecaries. Shop-keepers, tradesmen, and commercial men were wholly unfit to vote on such occasions. They subscribed to afford relief to the poor, and were incompetent to interfere in matters which they did not understand.—The resolution was carried unanimously.

Mr. Wray then defended Dr. Clutterbuck from a charge brought against him, of being physician to the Western Dispensary, whose laws were said to be similar to those of the institution in Aldersgate-street, which was not true. The fact was, that, at his request, Dr. C. allowed himself to be nominated consulting physician, but he knew nothing whatever of the laws of the charity; and every medical practitioner well knew that consulting physicians, or surgeons, were always in this position, as they were rarely called on to interfere.

Mr. Proctor then moved that the foregoing resolutions be inserted in the *Times*, *Morning Chronicle*, *Globe*, *Medical and Surgical Journal*, *Lancet*, and *Medical Gazette*.

Dr. Clutterbuck then rose to return thanks, as the oldest officer among his late colleagues, and after stating the pride he felt in having his and his colleagues' conduct so highly approved of by that, the oldest and one of the most respectable societies in the metropolis, he felt himself bound to explain to the meeting the real causes that led to the resignation of himself and his colleagues. He said that there were seven druggists on the committee, they supplied the drugs, audited their own accounts, and paid

their own bills. The fact was, that the committee were interested tradesmen who supplied the institution with every thing, and the late medical officers could not connive at such monstrous abuses. After numerous remonstrances on their part to the committee, against the abuses and the obnoxious bribery law, without effect, they were at length compelled to address a circular to the governors, in which they exposed abuses, and tendered their resignations in the event of the obnoxious law being carried. At the meeting of the old friends of the Dispensary, they (the medical officers) carried their point. But the committee were determined to succeed; they called another meeting of the governors, made a number of new ones, and out-voted the real friends of the charity. The medical officers now resigned, as they had intimated they should do, in the event of such a corrupt and obnoxious law being established.

Mr. Groom, one of the committee, asked permission to address the meeting in reply to Dr. Clutterbuck, as he could show that Dr. C. was not in a condition to prove his imputations.

The President said that according to the laws of the Society, none but members of the profession could take a part in its debates.

Dr. Birkbeck returned thanks, and ably explained the bad tendency of the law adopted by the Aldersgate-street committee.

[As this gentleman's sentiments were so very fully explained in our report of the meeting of the Westminster Society in our last, it is unnecessary to give them here.]

Mr. Salmon rose to return thanks, but before he did so, he wished to correct a statement made by his friend Dr. Clutterbuck, which was, that there were seven druggists on the committee. In fact, there are but three druggists on the committee, Mr. Herring, the treasurer, who supplied the drugs; Mr. Biggar, who supplied the chemicals, and Mr. Lucas, who supplied the inferior

articles; but it was true that they could, whenever they desired it, command the votes of other chemists, who had been made life governors. The committee were interested in supplying all articles, and paid themselves. They did not stop here, but when the medical committee, one of whose duties was to examine the testimonials of medical candidates, had refused to do so, as a meeting of the governors had been summoned to confirm or reverse the proceedings of the committee, this body made four chemists new governors, and these were brought to the dispensary to examine the testimonials. The treasurer or committee had no power to act in this shameful manner; and the present medical officers were elected illegally. He now adverted to his own conduct, and declared he did not obtain his appointment under the obnoxious law; in fact, he lost a former contest by it.

Mr. Coulson briefly expressed his warmest thanks for the honour conferred upon him by so distinguished a Society, and he felt proud that in defending a good principle, he forfeited his office.

Dr. Uwins moved that the President do leave the chair, and that Dr. Shearman take it.

Dr. Uwins then proposed a vote of thanks to the President for his impartial conduct as chairman, and this was received with acclamations.

MEDICAL SOCIETY OF LONDON.

At a general meeting of the Society, held on Monday, the 4th of November instant, William Kingdon, Esq. President, in the chair, the following resolutions were unanimously adopted.

Moved by Dr. Waller, and seconded by Dr. Williams,

- 1st. That in the opinion of this Society, the regulations recently recommended by the Committee and adopted by the subscribers of the General Dispensary, Aldersgate-street, by which the medical appointments are offered to the competition of the richest instead of the most talented

candidates, is injurious to the interests of the poor, the respectability of the profession, and utterly subversive of the object for which such institutions were founded.

Moved by Dr. Uwins, seconded by Mr. Dendy,

- 2nd. That Doctors Birkbeck, Clutterbuck, Lambe and Roberts, and Messrs. Salmon and Coulson, are highly deserving the thanks of this Society, for the spirited and praiseworthy manner in which they have stepped forward to oppose the making public Medical appointments matters of bargain and sale, and for resigning their offices, when they could no longer hold them without compromising their professional honour and independence.

Moved by Dr. Shearman, and seconded by Mr. Drysdale,

- 3rd. That the cordial thanks of this Society be given to H. R. H. the Duke of Sussex, for the zeal he has on all occasions manifested in patronising measures calculated to advance the interests of science, and particularly for the countenance and support he so promptly afforded to the late Medical Officers of the Aldersgate Dispensary, in their endeavours to uphold the dignity of the profession, and to promote the welfare of the sick poor.

Moved by Dr. Ryan, and seconded by Dr. James Johnson,

- 4th. That the Fellows of this Society exceedingly regret that any of their medical brethren should have so far forgotten the dignity of the profession to which they belong, and their own self-respect, as to have allowed themselves to be nominated and appointed to the vacant offices, trammelled as they now are by such an obnoxious regulation.

Moved by Mr. Proctor, and seconded by Mr. Cox,

- 5th. That the foregoing resolutions be published in the *Times*, *Morning Chronicle*, and *Globe* newspapers, and in the *Medical and Surgical Journal*, *Lancet*, and *Medical Gazette*; that copies of the votes of thanks, signed by the President on behalf of the Society, be transmitted to His Royal Highness the Duke of Sussex, and to each of the late Medical Officers of the Aldersgate-street Dispensary.

EDWARD HEADLAND, }
H. P. ROBERTS, } *Secretaries.*

LITHOTRITY. — Mr. Elderton has published several documents in the *Northampton Mercury*, proving that he was the inventor of the Lithotrite.

London Medical & Surgical Journal

Saturday, November 9, 1833.

THE LATE ALDERSGATE - STREET
 DISPENSARY.—THE TRUTH, THE
 WHOLE TRUTH, AND NOTHING BUT
 THE TRUTH.

“Fruiturque famâ sui,”

Tacit. Ann. ii. xiii.

IN resuming this subject, which every week acquires a greater interest in its practical bearings, we must beg our readers to call to mind, that, on a former occasion, we stated, in general but very distinct terms, the real nature of the matter at issue before the public.

Undoubtedly the purity of medical elections is a point of paramount importance; and the fraud, which the Committee attempted to practise upon the profession, will still furnish us with a topic of great interest, in our further endeavours to expose the machinations of the designing, and to effect a general and salutary reform in the medical appointments to public charities.—We shall not at present descant further upon this head of the Aldersgate-street Hydra. To-day we have to illustrate that part of our statement, which pointed at certain other frauds in the conduct of the Committee, as the foundation of the whole affair. It was by a vain attempt to stem these latter, that the late Medical Officers incurred the unforgiving hatred of the wrongdoers; and in consequence were artfully disgusted into a resignation of their offices by the manœuvre of the obnoxious medical appointment law.

The conduct of the London Medical Society, on Monday last, fully justified our expectations. The sentiments of all the speakers, who addressed the meeting on the general question, so fully accord with the tenor and spirit of our remarks at former times, that we shall content ourselves for the present with referring to the resolutions of the meeting, in another part of this Journal. By far the most interesting part of the proceedings, in reference to our preceeding observations, was the plain and manly statement which Dr. Clutterbuck and Mr. Salmon were induced to make, in acknowledging the approbation of such an influential body of the profession. It is to this statement we desire to call the attention of the public. The facts disclosed in it illustrate the true origin of the contest in which these gentlemen have been engaged. The public is now enabled to probe the matter to the quick. Pounds, shillings, and pence every man can understand, and every man can appreciate the propriety or impropriety of measures emanating from so foul a source as the love of pelf,—albeit he can persuade himself the unanimity of a numerous, respectable, and disinterested profession, upon a matter affecting their respectability, their professional acquirements, and independence, is not the test of truth. The true motive of the new election-law of the Dispensary is now brought to light.

It will be seen, from the report of the meeting in the public papers, and in our Journal (for we desire to be

exact), that Dr. Clutterbuck, in explaining the motives of his conduct, stated, "that the Committee of the Dispensary was made up of tradesmen, who were deriving profits from the institution in various ways, and who, with a view to those profits, made regulations, to which he felt he could not, with a due regard to the dignity of the profession, conform—that there were no fewer than seven druggists upon the Committee, and they ordered what was wanted, and examined and paid their own bills, and that the offices of druggist, chairman of the Committee, and treasurer were united in one person." In pursuing the same observations, Mr. Salmon said, that strictly "there were only three members of the Committee who were druggists: the treasurer, Mr. Herring, who supplied the drugs; Mr. Biggar, who supplied the chemicals; and Mr. Lucas, who supplied a small quantity of inferior articles; but it was true they could, if they desired it, command the votes of three other chemists, who had been made Life Governors." Comment upon such details is superfluous. No wonder the medical officers of the establishment, who had dared to avow their disapprobation of such a system of partnership, and its consequences were odious to the Committee. No wonder the most efficacious means were adopted, to force the resignation of such hated monitors, and to secure the appointment of persons, from whose independence no apprehensions were to be entertained.

Another instructive quirk of ma-

nagement was exhibited, on the late occasion, in the mode in which the medical testimonials of the new candidates were examined. It may be fairly conceded, this examination was, on that occasion, a very unimportant trust; and we give those concerned the benefit of the excuse at its full value. This duty, by the rules of the charity, should have devolved upon a Committee of Governors, who were of the medical profession. That Committee, when summoned after the resignations, refused to act till a meeting of the Governors generally should have decided upon the charge then pending against the Committee. The authorities were not to be baffled:—an appointment of four chemists in the neighbourhood as Governors was soon got up; and these latter *professional* gentlemen, some of them, we verily believe, not being aware of what they were doing, or wherefore, performed their parts in the farce to admiration, and the managers were eased of the old, sturdy, medical Committee! Look to these things, Subscribers!

MEDICAL REFORM.—VIEWS OF THE PROFESSION.—INTENTIONS OF GOVERNMENT.

"Quanto summæ spei propior, tanto impensius." *Tacit. Ann. i. xxxiv.*

AFTER our late account of the operations of the College of Physicians and their *classical* President,—after even that tardigrade body has become "restless, unfixt,"—it may be readily imagined what intense anxiety is felt upon the subject of medical reform, and how busy are the thoughts of the thinking part of the profession, as the

time approaches when reflection shall spring into action. In the interval, it shall be our duty to discuss anew the leading parts of the general question ; and, without pledging ourselves to any new-fangled scheme, or self-interested party, we shall proceed upon the broad principles of public policy, and professional respectability, to discharge that debt which Lord Bacon says every man owes his profession, and canvass, with candour, the various opinions which are entertained on the subject by the leading parties or persons.

The Profession will observe with much interest that Dr. Somerville has given notice that he will propose the discussion of medical reform at the Westminster Medical Society in a fortnight from this date. By this means thoughts will be brought into collision, and men's minds will be prepared for that more searching inquiry, which will take place before Parliament in the next session. In the mean time we will take the liberty of assuming the office of Moderators, and suggest a seasonable rule for the conduct of the argument.—It is, very simply, to beware of dogmatising. There is still much information to be elicited before we have all the data for the solution of such an intricate problem. The opinions of the Profession will have great weight with the Legislature ; and we would not have them too rashly “ jump to a conclusion.” These observations are particularly addressed to those who intend taking a part in the debate.

Since our last number we have re-

ceived some slight intimations—satisfactory in their nature—of the intentions of Government relative to the approaching investigations. For these we are indebted to the frank communications of Mr. Littleton to a deputation of the National Association of Apothecaries in Ireland, to inquire into the nature of the reform contemplated by the Administration. This body and its able President, Mr. Donovan, is a serviceable ally in the cause of medical reform. The Chief Secretary of Ireland declared his opinion of the necessity of obtaining much further information before the work of legislation should commence ; that he expected some hon. member (perhaps Mr. Warburton) would move for a select committee, with full powers to obtain the necessary evidence, to enable Parliament to legislate consistently and comprehensively ; and that “ he thought it highly probable that ultimately three separate bills would be enacted to regulate the professions of physicians, surgeons, and apothecaries, each of which should obtain a distinct and uniform code for the particular profession, with a view to its assimilation throughout the three kingdoms, and thus no longer to leave its practitioners the sport of laws often differing widely in principle, and, if they ventured to change the scene, conflicting in practice too.” The absurdities of the present system cannot be more vigorously compressed into a text than in these latter words. “ Mr. Littleton expressed himself decidedly convinced that the wants of the poorer classes

throughout the empire required that the apothecaries should, in addition to a knowledge of pharmacy, possess that of surgery; but he was not prepared to uphold the converse of the proposition, and seemed to think that the study of pharmacy should be left optional with surgeons."

Such are the main details of this important interview. We must reserve some remarks upon the opinions it broaches for another occasion.

COLLEGE OF SURGEONS.

IT is with much pleasure we announce that the College has purchased a house adjacent to the Museum, on the site of which it is intended to erect a wing to their present building. They will thus have convenient room for their extensive library, and be enabled to display the increasing treasures of their museum. The cost is to be £10,000. The College has at present a capital of £60,000.

MISREPRESENTATION.

A CORRESPONDENT sent us last week a very angry remonstrance against a gross deliberate misrepresentation contained in a letter admitted, without note or comment, into the pages of "*The Chlorosis of Medical Literature*," under the signature of a Fellow of the College of Physicians. The letter in our cotemporary bore internal evidence of having come from head quarters. That the truth was not in it was palpable to the merest tyro of a licentiate. Mere mistake prevented the insertion of our correspondent's

letter in due time, and as there is a palinode, in the shape of another letter, in last week's number of the original offender, it is unnecessary to break a fly upon the wheel by publishing our correspondent's indignant letter.

MEETING OF GENERAL PRACTITIONERS.

WE understand that a meeting of the Profession is to be held on Friday, the 16th inst., at half-past seven o'clock in the evening, at the Sussex Hotel, Bouverie-street, Fleet-street, to take into consideration the infringements made upon the profession by unqualified persons and to confer on the most efficient mode of removing this injustice.

We are glad that the General Practitioners, who are the physicians, surgeons, and apothecaries of the great bulk of society, and who do not keep open shops, or vend chemicals, quack medicines, &c., have at length come forward to vindicate their respectability. We have always considered this class as useful and as respectable as any other in the profession; but we denounced those of that body who vend fire-boxes, &c., who confound themselves with uneducated chemists and druggists.

MEETINGS at Nottingham, Macclesfield, at Colchester,—of the Medical Society, Cork, and several places have lately been held, at which the unanimous thanks of the medical profession were given to the late Medical Officers of the Aldersgate-street Dispensary. The noble and magnanimous conduct of the then officers has been duly appreciated by the profession in this kingdom, and will, no doubt, receive applause throughout the medical world. We find that so much of our space has been occupied with addresses to them, that we cannot henceforth occupy our pages with further communications of this kind, as, indeed,

they are unnecessary. We shall, however, feel much pleasure in noticing any that may be forwarded to us.

DINNER TO DR. CLARK OF GLASGOW.

ON Tuesday last a dinner was given to Dr. Clark, in the Tontine Hotel, Glasgow, by a number of gentlemen, in token of their sincere respect for him, previous to his leaving Glasgow to commence his duties as Professor of Chemistry in the Marischal College, Aberdeen. Colin Dunlop, Esq. was in the chair, and Charles Tennant, Esq. officiated as croupier.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, October 31st.

George Henry Doswell	Romsey, Hants.
Thomas Richard Fisher	Oxford.
Denham Melancthon	} Tregony.
Jewel	
Edmund Harwick Marriott	Needham Market.
Wm. George Fred. Payne	Frome.

BOOKS.

Surgical Observations on the Restoration of the Nose, and on the removal of Polypi and other Tumours from the Nostril, from the German of Dr. Dieffenbach, of Berlin, with the History of the Rhinoplastic Operation. By JOHN STEVENSON BUSHNAN, M. R. C. S., &c. 8vo. Pp. 155. Twenty-six Plates. London, 1833. Highley.

The Glasgow Medical Journal, conducted by WILLIAM WEIR, M.D. and JAMES ADAIR LAWRIE, M.D. October, 1833.

Traité de la Vaccine et des Eruptions Variolieuses ou Varioliformes, ouvrage rédigé sur la demande du Gouvernement. Par M. J. B. BOUSQUET, M.D. 8vo. Paris and London, 1833. J. B. Baillière.

The Dublin Journal of Medical and Chemical Science, &c. Editor, Robert J. Kane, Esq., Professor of Chemistry to the Apothecaries' Society, &c., &c.

Report of the Sussex and Brighton Infirmary for Diseases of the Eye. 1833.

Chemical Diagrams, accompanied with a Description of each Decomposition, the Vegetable Alkalies, the Urine and Urinary Calculi, and Tables of Chemical Equivalents. By ALEXANDER LEE, A.M., Surgeon. London: 1833. 12mo. pp. 182. E. Cox.

Nos. V. and VI. of the Animal Kingdom, arranged according to its Organisation, serving as a Foundation for the Natural History of Animals, and an Introduction to Comparative Anatomy. By BARON CUVIER, Great Officer of the Legion of Honour, Councillor of State, &c., &c., &c.; with figures designed after Nature. Translated from the latest French edition, with additional Notes, and illustrated by nearly 600 additional Plates. London. 1833. G. Henderson.

The First Part of the ninth edition of the Gardener's Dictionary, containing the best and newest methods of cultivating and improving the Kitchen, Fruit, and Flower Garden, and Nursery, as also, for performing the practical parts of Agriculture, &c., &c., &c. By PHILIP MILLER, F.R.S., formerly Gardener to the Worshipful Company of Apothecaries, at their Botanical Garden in Chelsea, and Member of the Botanic Academy at Florence. London. 1833. G. Henderson.

A Series of Anatomical Plates, with References and Physiological Comments, illustrating the Structure of the different parts of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy and Physiology in the University of London. 1833. Part II. John Taylor.

Principles and Practice of Obstetric Medicine, in a Series of Systematic Dissertations on Midwifery, and the Diseases of Women and Children; illustrated by numerous Plates. By DAVID D. DAVIS, M.D., M.R.S.L., Professor of Midwifery in the London University, &c., &c. Part XXV. John Taylor.

CORRESPONDENTS.

M. R. C. S.—We should give the names of the gentlemen who pass the College of Surgeons every week, but the ruling powers in that quarter withhold their consent.

P. P. P. should have paid the postage. It is really too bad that correspondents should put us to expense in answering questions solely relating to themselves. In future we shall not notice a single communication unless the carriage has been defrayed.

Dr. Slade.—We are much obliged for the contribution, and shall insert it at our earliest convenience.

Mr. Wallace's communication as soon as possible. He shall hear from us by Monday next.

Mr. Atkinson's letter is under consideration.

Mr. B.—We shall give Dr. Stokes's lectures on the Practice of Medicine, and Dr. Graves's on the Theory or Institutes of Medicine, alternately.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

No. 94.

SATURDAY, NOVEMBER 16, 1833.

VOL. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXIII., DELIVERED MARCH 6, 1833.

GENTLEMEN,—You are not to suppose, that necrosis never attacks the articular extremities of bones; it is true, that it is not much disposed to do so; but the occurrence is sometimes noticed, as is exemplified on the head of this tibia, a great part of which is in the state of necrosis. The case, from which it was taken, proves the truth of an observation delivered in the last lecture, namely, that, when the head of a long cylindrical bone, one that enters into the formation of a considerable joint, like the knee, is involved in the ravages of necrosis, amputation may become necessary. You may observe in Wiedmann's excellent work on necrosis, now before us, representations of several of the most interesting circumstances, which take place in this disease. We had on the table, at the last lecture, a preparation, showing the extension of necrosis so far up the shaft of the femur, that the head of the bone was attacked by it: this was a case which followed amputation of the thigh; but in ordinary cases only the shaft suffers, and the end of the bone, or that which is disposed to protrude from the stump, is attacked; this in time exfoliates, and the part then heals up, without any further occasion for another operation. The engraving, to which I now beg your attention, shows the protrusion of the dead shaft of a humerus through the skin, in such a way, that it admitted of being taken out with the fingers: and here is a representation of the sequestrum after its removal. It is curious to notice, that the lower portion of the dead bone is generally more angular and irregular than the upper. Here are engravings, exhibiting the appearances of necrosis in the os frontis, and also in the tibia. In some of these fine and accurate plates, the

drawings for which were all taken from nature, you have views of the *cloaca*, or apertures, which I described to you, as forming outlets for the matter collected between the sequestrum and new bone. There are also several plates in the work, representing necrosis of the articular extremities of bones, and here is a very remarkable one, in which there are not less than three sequestra, one in the upper head of the fibula, and two in that of the tibia. If ever you should have occasion to make any researches on the subject of necrosis, I should recommend you to look over Wiedmann's matchless work, for the correctness of the descriptions in it correspond fully to the beauty of the engravings. One of the plates represents a regeneration of the lower jaw; here it is; the case was a necrosis of that bone, and you see the reparation of the mischief which has been effected by nature, and the appearances of the new bony formation—how well it has served as a substitute for the original bone.

In the treatment of necrosis, gentlemen, it is necessary to consider that the disease presents itself in three different stages. *The first is attended with inflammation, and is that in which the disease is forming.* In the *second stage, the sequestrum, or dead bone, has been produced, but it is still fixed, and firmly connected to the living parts of the bone.* In the *third, the sequestrum is not only formed, but loose.* Now such varieties in the condition of the disease have a considerable influence on the choice of plans for adoption, with a view of promoting the cure.

In the *first stage*, supposing the disease to be extensive, and to be accompanied by severe inflammation of the soft parts, while the sequestrum is only forming, it is manifest, that you can do little more than endeavour to check and moderate the inflammation of the soft parts. In this stage of necrosis you are to have recourse to antiphlogistic treatment, especially the application of leeches, fomentations, and poultices, and sometimes you may cup the part with a better effect, than what is obtained from the other form of local bleeding. It is evident from the very nature of the disease, namely, from the circumstance of its unavoidable

able and speedy complication with a portion of bone, entirely deprived of all vital action in it, which dead piece of bone must then be regarded as an extraneous substance; that the utmost we can do in this stage, is to lessen the inflammation and appease the patient's sufferings; the sequestrum will inevitably be produced, and must be got rid of before a cure can be accomplished. In the early stage of the disease, gentlemen, one principal indication is to let out matter directly it has formed; and I wish to impress upon your minds the fact, that, in these cases, the matter is a good deal confined; it is mostly under the periosteum; and, in many instances, a deep and free incision is necessary for its evacuation. Always remember, then, that the early and efficient discharge of deep-seated abscesses, is one of the most useful measures which can be pursued in the treatment of the first stage of necrosis.

In the *second stage*, or that in which the sequestrum is completely formed, yet firmly attached to the living part of the bone, the surgeon is generally obliged to wait till nature has more or less detached it, before he can take any useful steps for its removal: we know of no medicines that would have the effect of quickening the process of exfoliation; and even when the whole shaft of a bone is in the state of necrosis, it is by the process of exfoliation that its separation from the living extremities of it is to be effected. You could not, in such a case, extract the dead bone without a great deal of difficulty, unless exfoliation were somewhat advanced. You may generally know, that the disease is in the second stage, by observing the presence of *fistulae*, through which you may commonly feel some part of the sequestrum on introducing a probe.

The *process of exfoliation*, or that by which the dead portion of bone is loosened and separated from the rest of it, is a particularly slow one, sometimes requiring months and even years for its completion. Though the process is analogous to that, by which sloughs are detached, it differs from it in requiring a much greater time; and, unfortunately, we have few means by which we can influence it in this respect. Some surgeons try counter-irritation; they apply blisters for the purpose of expediting the process of exfoliation; this plan was strongly recommended by the late Mr. Crowther, in a good practical work, which he wrote on the subject of necrosis and diseases of joints, and at one time such treatment was extensively adopted in some of the London hospitals. I believe, that counter-irritation, with blisters, or issues, may tend in some degree to quicken the process of exfoliation, and, at all events, it is often beneficial in lessening the disposition to repeated attacks of inflammation in the deeper parts of the limb, the recurrence of painful and profuse abscesses, and all the severe constitutional disturbance which is so liable to arise from these states of the disease. In necrosis, gentlemen, the health

suffers, not merely from the discharge which is so copious and long kept up, but from the repeated recurrence of fresh inflammation, and renewed formations of matter, after other abscesses have been nearly, or quite cured. You may also essentially serve the patient by supporting his strength; for, when he is languid and debilitated, or much reduced by hectic complaints, the process of exfoliation will not go on so well, as it would do if the actions and functions of the system at large were carried on with more vigour and less disturbance. We know, that exfoliation naturally proceeds more quickly in young persons than old ones, which may be regarded as fortunate, because a large proportion of the worst forms of necrosis happen in young subjects. However, notwithstanding all you can do, by means of tonics, assisted with an eligible diet, notwithstanding the most judicious support and regulation of the general health, a complete cure of necrosis, in its second stage, by natural processes, that is by the complete absorption, or annihilation of the sequestrum, and the subsequent healing up of the fistulous openings, is not frequently accomplished. Yet we have, at this present time, a young girl at the Bloomsbury Dispensary, in whom a necrosis of the upper portion of the humerus seems to have terminated in this very favourable manner. In the generality of instances, very active and sometimes remarkably bold measures become necessary, but these can seldom be adopted with any success during this second stage of the disease, unless you were absolutely compelled to amputate the limb; for if the health should be so dangerously reduced and deranged by the pain and irritation, and profuse discharge, that a further perseverance in the attempts to save the limb would be more likely to lead to the patient's death than the cure of the necrosis, you would then be called upon to amputate the limb. In fact, this necessity occurred in the case illustrated in the engraving before you, in which there was a necrosis of the condyles of the femur and of the head of the tibia; here the health was so seriously affected as to render further attempts to save the limb improper, and the operation was performed.

In the *third stage of necrosis*, or that in which the sequestrum is loose, the dead bone can only be regarded as an extraneous body, keeping up more or less irritation and suppuration. Its removal, therefore, either by natural processes, or by the interference of the surgeon, is now necessary for the cure. Sometimes one end of the sequestrum will actually make its way through the skin, and will protrude, as happened in the case from which this engraving was taken, and then it may be easily taken away; but, in other instances, its removal will be more difficult, as where it is completely surrounded by a new bony tube: then an operation will mostly be required sooner or later, for the purpose of extracting it. In very young subjects, it has sometimes been

removed by natural processes, even though thus circumstanced, but, in general we are obliged to cut away a portion of the new osseous deposition that confines it. But, first, it is necessary to ascertain whether there is really a sequestrum present, and whether it is loose—information which may generally be ascertained by means of a probe. You are to be careful to form a correct judgment on these points, for very useless and painful operations have sometimes been performed after the sequestrum has been actually absorbed. On this account, *when you find the health pretty good, the discharge lessening, and the fistulous openings inclined to heal, it is the best practice to leave the case to take its own course.* At all events, here there is no urgency for any operation, and let nature have time. *But where the health is suffering dangerously, and the sequestrum is known to be loose, that is, can be felt to be so, it becomes an object to remove the dead bone from the osseous canal,* in which it is confined, and which is frequently so hard as to require the saw or trephine. Suppose the sequestrum to be surrounded by a bony tube, you should make an incision on that part of the new osseous formation, under which you have ascertained with a probe, that the loose dead bone is situated. Having done this, you will generally see the cloacæ, through which you make another examination of the state of the sequestrum with a probe. Then, by cutting the interspaces between these apertures, some of which, as you see in this preparation, are rather large, you will sometimes succeed in making sufficient room for the extraction of the sequestrum, which may be divided itself, if that will facilitate its extraction piecemeal. At all events, as much of the bony case, as will enable you to get at and remove the dead bone within it, must be cut or sawn away. After the dead bone has been exposed to a sufficient extent, it should be divided with cutting-pliers, like those which I now show you, and then the fragments are to be taken out through the same aperture. There are several reasons why you should avoid making openings in different parts of the new bony case: in the first place, such practice would destroy too much of the new bone; secondly, the soft parts would be injured by it to too great an extent. Suppose you could not succeed in removing the proper extent of the osseous case with the cutting-pliers, which a remade strong enough to cut through any bone of a moderate thickness and consistence, then you should use a saw, and the saws employed by the late Mr. Hey are particularly convenient for the purpose. Sometimes the application of a small trephine becomes necessary. This is one of Mr. Hey's straight saws, but those, which have a semicircular edge, are frequently the best for cases of necrosis, as they will divide the bone in any direction you please. You will also find an elevator particularly useful in removing the sequestrum.

It commonly happens, that the sequestrum

does not extend through the whole length of the tube, and only certain portions of the original bone are destroyed, in the manner you see delineated in this plate; consequently, the new bony formations are then only at particular points.

I have already informed you, gentlemen, that, in unfavourable and extensive cases of necrosis, amputation sometimes becomes indispensable, because the patient's constitution cannot bear the repetition of operative proceedings necessary to get away every part of the dead bone, for it frequently happens that you cannot remove all the sequestrum at once, and then several operations may become necessary. In the course of the treatment, tonic medicines will usually be needed, and sometimes, also, on account of the frequent attacks of inflammation, these must be combined with antiphlogistic means. In the course of a year, there may be from eight to sixteen attacks of severe inflammation of the soft parts, followed by new abscesses on each occasion, and, under these circumstances, reluctant as we may be to do any thing to weaken the patient further, we are compelled to employ local bleeding and other antiphlogistic remedies in moderation. Then, gentlemen, if you consider the unavoidable irritation and drain upon the system, produced by the long continuance of the disease, you will not be surprised if, in many instances, the patient should be reduced so low by hectic fever, that amputation is the only chance of preservation remaining for him. Do not, however, take off the limb unnecessarily; remember that nature will do a great deal for the patient in this disease, and, as I have explained, it is in the osseous texture that she possesses, perhaps, a greater power of repair and reproduction than in any other tissue of the body.

The next disease of the bones for your consideration is *mollities ossium*. This is a very rare affection, and one that is sometimes confounded with rickets, though erroneously. In mollities, the bones become preternaturally soft and flexible; those of the lower extremities may indeed, in some instances, be bent in such a degree, that the outer ankle can be brought against the temple without the femur being fractured. It is, as I have said, an exceedingly rare disease; I never saw a case of it, nor have I heard of a single example of it in St. Bartholomew's Hospital during the last thirty years. However, there are well authenticated cases of it on record, and therefore I think it right you should know that there is such a disease. In the natural state, the bones contain more than half their weight of earthy matter, and I believe that, in some instances, the proportion of earthy matter amounts to nearly two-thirds of their whole weight. But, gentlemen, in mollities ossium, in the morbidly softened state of the bones to which I am referring, the earthy matter is only in the proportion of one-fifth part to four of the animal matter in their composition, and sometimes

even less. It seems to me, that there are several points in which a striking difference prevails between mollities ossium and rickets. In the first place, mollities ossium is a very rare disease, whereas rickets is particularly common. Mollities ossium hardly ever takes place except in females, and in those who are above the middle period of life; whereas rickets attacks chiefly children, or, at all events, those who are under puberty. Another distinction is, that in rickets the earthy matter has been originally deficient; the bones have never been properly developed from birth; but in mollities ossium, the bones attain their full growth, their texture is perfect, and their proportion of earthy matter is quite right, until about the middle period of life, when those peculiar changes in the texture of the osseous system take place, which constitute the disease under consideration. The disease appears to arise from some defect in the nutrition of the bones; but the exact cause of it is not understood. You will sometimes find writers confounding *mollities* with *fragilitas ossium*, but this is erroneous on many accounts; the two diseases seem to me to be the reverse of each other. Thus, when the thigh-bone is so soft that the outer ankle can be placed against the temple, this must be a different case from fragility, in which the bone cannot be bent at all without breaking. Sometimes in mollities ossium nearly the whole of the natural texture of the bone is absorbed, and but few vestiges of it remain. A bone in this state is found to contain cells, filled with a brown or livid substance, and having communications with the cells on the outside of the bone, or, in other words, with the cellular membrane. When the osseous system is thus affected, of course it is disqualified for its functions, as it can no longer support the limbs, nor will the bones, thus altered, serve as levers for the muscles to act upon: neither can they afford that protection to the important parts which we find they are frequently designed by nature to give. Hence, in the worst forms of mollities ossium, the stature is so much altered, that persons afflicted with this disease, who were originally five or six feet in height, become not more than two:—thus Madame Supiot, whose case, I believe, is the most remarkable one on record, was, at the period of her death, only twenty-three inches in height. In her case, there was also such a change in the shape of the bones, that the compression of the thoracic viscera was probably the circumstance which mainly contributed to put an end to her miserable existence. Her limbs could be bent in the extraordinary manner I have explained, without breaking. Mollities ossium, as far as all our present information about it reaches, is invariably and certainly a fatal disease; for there is no instance of it on record, in which a cure has been effected; and, whenever it occurs, there is immense disturbance of the constitution; in particular, the patient usually has constant and profuse perspiration; a very copious deposition of phos-

phate of lime takes place in the urine, and a great deal of fever occurs. Here, you may observe, there is a vast difference between this disease and rickets; in this last disease, there is not necessarily any severe degree of constitutional disturbance; the disorder is not the cause of any fever or pain. But, in mollities ossium, the patient's sufferings are truly deplorable, and the health is universally and totally deranged. In rickets, you see no profuse sweats, no copious deposit of phosphate of lime in the urine. When I make these observations, it is not my meaning that you may not have rickets combined with very bad health; but, when this is the case, the complication is only an accidental and not an essential one. You may have marasmus and great constitutional disorder with rickets, or not; and, as in dwarfs, it is not uncommon to observe in rickety children a great precocity of the mental faculties. for the treatment of mollities ossium, I have already told you that the disease is regularly a fatal one. The phosphate of lime has been tried internally, on the supposition that there is a deficiency of that earth in the system; but this notion is quite hypothetical. Though an unusual quantity of phosphate of lime seems to be thrown out of the system by the kidneys, it does not follow, as a matter of course, that there must be any want of it in the constitution. The fault lies probably in some inexplicable derangement of nutrition of the osseous system, either interfering with the regular deposition of that substance, or causing its too rapid absorption and conveyance out of the system. It seems unnecessary for me to say any thing about tonic plans; every thing has proved inefficient. But, gentlemen, as a very curious disease, I considered it right to say a few words respecting it, and its distinction from rickets and *fragilitas ossium*, although it is equally rare and incurable.

Gentlemen, the next disease on which I mean to make a few remarks, is *fragilitas ossium*, which consists in an unnaturally brittle state of the bones. When I was on the subject of fractures, I mentioned the influence of particular diseases in rendering the bones liable to be fractured by very slight causes. You may remember, I informed you, that in the advanced stages of syphilis, in cancer, in fungus hæmatodes, in scrofula, and in scurvy, so great a weakness and fragility of the texture of the skeleton are sometimes created, that fractures will take place from the most trivial causes, so trivial, that those are sometimes termed *spontaneous*. We had on the table one evening, a thigh-bone, which had been fractured as the patient was merely turning himself in bed, and the accident happened while he was taking mercury for nodes on the opposite thigh-bone, which is also in the University museum. Here is another specimen, in which the humerus was broken by shampooing; the patient had scrofula, and while the limb was undergoing the shampooing process, the bone broke; this first

fracture united; but a second fracture happening afterwards in another place, a false joint formed in the situation of the injury. These facts are plainly seen in the preparation. The bone was so brittle, that when the surgeon was dissecting it after death, it broke in a third place, as you may perceive.

In old age, there is always a degree of fragilitas ossium, and this is generally explained by the circumstance, that, in the bones of old persons, there is a large proportion of calcareous matter to the animal and vascular matter in them. However, the bones of aged individuals are not so brittle as to crumble away; on the contrary, they are found to contain a great quantity of greasy matter; you will find, when you wish to make a skeleton, that if you take an old subject, you will never get bones perfectly clean; they will always look greasy, and you cannot make them white. The other varieties of fragilitas ossium are attended with a diminution in the quantity of phosphate of lime; and when there is really an increase in its quantity, it is, I believe, only in that form of fragilitas ossium, which comes as the natural effect of old age. In all the other forms of this disease, the bones are generally lighter than natural. The fragilitas ossium of old age is of course incurable. In other examples of it, arising from different diseases of the constitution, the cure will entirely depend on the possibility of curing the original disease; if this can be cured, there will be a chance of the proper texture of the skeleton being restored; but under other circumstances, no hope of a cure can be entertained.

I was called some time ago to a patient, whose thigh broke as he was turning in bed; it appeared that he had a cancerous disease of the bladder, for after death a large fungous tumour was found in his bladder, situated upon so hard a cartilaginous base, that when felt through the bladder, it was at first supposed to be a stone. One of the ribs was also broken, and both this fracture and that of the femur were surrounded by a mass of scirrhous matter.

Gentlemen, the next disease for your consideration is *rickets*, or *rachitis*, as it is termed. It principally affects children, and mostly between the ages of eight months and three years. I have already told you, that many writers confound this disease with mollities ossium; but this is a mistake; for there are not only the differences I have mentioned between the two diseases, but some others. In mollities ossium, the bones may be bent without breaking, but in rickets they cannot be bent without being fractured, so that there is a degree of fragilitas accompanying the disease. In rickets, the bones have never from birth contained their due proportion of phosphate of lime; while in mollities ossium, the bones reach their perfect development, but after the individual has attained the middle period of life the changes take place in them

which I have described. Then, in mollities, there is not that thickness of the bones of the cranium, which is commonly observed in rickets; sometimes, indeed, the thickness is immense. As a specimen of a thick skull in a rickety subject, you cannot meet with a better one than what I now show you. As Mr. Shaw has observed, the derangement of the minute textures is exhibited in the skull in a remarkable manner, some parts of the calvarium having an extraordinary thickness, while other parts of it are reduced to the thinness of paper, and the divisions of the tables are lost. Sometimes the parietal bones become seven-eighths of an inch in thickness, while in the situation of the fontanelle and sutures the cranium is surprisingly thin. Mr. Shaw mentions a skull-cap, taken from a child between three and four years old, where the bones were in some places seven or eight lines in thickness, and when squeezed, blood and serum issued from their interstices. This specimen was shown by Hunault to the Academy of Sciences. When the bones have once become affected with mollities, they never recover their natural texture, and sooner or later, the disease proves fatal; but in rickets the bones often acquire in time a better shape and a greater degree of firmness; indeed, they often acquire such a degree of firmness as fits them perfectly for the performance of their functions; and some rickety children grow up to be very athletic subjects. When the disease, however, is in an aggravated form, the deficiency of phosphate of lime is sometimes so great, that nothing but the shell of the bone is left, the internal part being filled with cells containing a red sanious fluid. Although there is in this circumstance a degree of resemblance between rickets and mollities ossium, it is to be recollected, that the bones in the former disease cannot be bent as they can in the latter. With respect to the change in the bones, it does not merely consist in that deficiency of the secretion of phosphate of lime; in addition to the loss of firmness from that cause, there is a disorganisation of the minute textures of the bones—and this is so much the case, that, in aggravated cases, the walls of the long cylindrical bones may be entirely removed, and the whole interior preserves, according to Bichat, a homogeneous appearance, and consists of cellular texture throughout. Here truly you might have mollities and flexibility; but these are extreme cases, such as are not usually met with.

It is curious to observe the efforts, made by nature to obviate the effects liable to occur from the weakness of the bones in rickets. You will generally find, if you examine a bone that is bent by the effects of the disease, that in proportion as the walls of the larger curvature are thinned, the walls of the lesser one are thickened and strengthened; you see this illustrated in several of the rickety bones before us. The reason of this is, that the lesser curvature has all the weight of the body

to support, and, if there were not this provision made, the bone would be incapable of supporting any weight. For some valuable observations on this subject, we are indebted to Mr. Stanley. There are preparations in the museum which shew the thickening of the lesser curvature of rickety bones, better than the bones you are now examining, though these will give you a very good idea of it. You see, that the wall of the lesser curvature is thicker and stronger than that of the larger one.

Next, gentlemen, I wish you to observe, that one effect of rickets is to flatten the long cylindrical bones, and that the greater diameter of the bone, when thus flattened, is always from the fore-part of the curvature backwards; thus the same effect is produced as what results from the wall of the lesser curvature being thickened—the bone is strengthened by it. This change is well shewn in the bones, which I now pass round for your inspection. When the cylindrical bones are affected with rickets in an extreme degree, the medullary canal is sometimes obliterated, in consequence of one side of the wall of the bone acquiring an immense thickness. This preparation was sent in as an example of the change in question; the medullary canal is certainly obliterated, but I do not think that it has happened in this instance as a consequence of rickets.

It has been supposed, that the heads of rickety bones expand; but this is found not to be the case: the joints certainly seem very large in this disease; yet this is proved by dissection to depend principally upon the emaciation of the soft parts. At one time, too, it was imagined that, in rickets, the periosteum was thickened; Beclard was of this opinion; but subsequent investigations have proved that such is not the case in any common examples of the disease. Here is a tibia showing the remarkable thickening, which the walls of the lesser curvature undergo.

We do not find, that the bones of the upper extremities are generally much deformed in rickets; for it is principally the weight, which the bones have to support, that produces the deformity of those of the lower limbs, and therefore such bones are principally affected with deformity in rickety children. Certainly it is not often that you meet with deformity in the bones of the upper extremities. The preparation which I now show you, therefore, is to be considered as a rare one; the humerus, you see, has been twisted by the action of the muscles, in consequence of which the ulna has been moved partly into the place of the radius, and the radius displaced. The upper head of the latter bone, no longer having the humerus to play upon, is elongated, and altered in its shape. Examples of deformity of the upper limbs from rickets are rare, compared with those of the upper extremity. We have another instance of it, however, in this subject, in which you will see an extraordinary deformity of each humerus produced by the pres-

sure of crutches. The skeleton is that of a boy, about ten or twelve years old, and it shows various other interesting circumstances connected with rickets; for example, it exemplifies the slow development of the teeth, and the imperfect formation of the alveolar processes, occasionally noticed in rickety children. The preparation is interesting on another account, for here the rickets was complicated with a scrofulous affection of the spine—a scrofulous caries of the vertebrae. Many writers incline to the belief, that rickets is essentially connected with scrofula; but this is an erroneous opinion; sometimes scrofula may be accidentally joined with rickets, as in this instance, but we frequently meet with rickets where there is no scrofula in the system. The skull of this subject is also surprisingly thick, more than an inch, I believe, in some places; and you will find, if you study the state of many of the bones, that they and their processes are but very incompletely developed. This is certainly the case with the vertebrae.

It was an observation, made by the late Mr. Shaw, that, in whatever state of distortion the spine and ribs may be, the bones of the pelvis will not be found distorted, unless there be at the same time marks of rickets in some of the long and solid bones; and it is argued by his brother, that as neither the bones of the upper, nor those of the lower extremities become incurvated, *when the distortion commences near the age of puberty*, it follows, that a cause, totally different from rickets, gives rise to it, and that the pelvis incurs no danger of being implicated in this deformity. Mr. Alexander Shaw, therefore, considers those skeletons only as true specimens of rickets, in which the distortion is exhibited throughout all the osseous system together—in the skull, the cylindrical bones of the extremities, and the large bones of the pelvis, as well as in the spinal column and the thorax. The figure of a rickety skeleton is distinguished by the head, the thorax, and the arms being preponderating and large, while the pelvis and lower extremities are, in a relative degree, diminutive and short. In the examinations of skeletons, made by Mr. A. Shaw, it was found that all the bones were to a certain degree deficient in size; but that such want of development was much more considerable in the lower half of the skeleton, the vertebral column and arms scarcely losing one-fifteenth of their natural length, while the bones of the lower extremity lose one-third of it. In the pelvis, the bones wanted nearly a quarter of their natural size. Hence, when the pelvis is deformed by rickets, it is not only those diameters, which are contracted by the thrusting inwards of the bones that are smaller than usual, but all the diameters are less than natural; whereas in the deformity of the pelvis from mollities ossium, in proportion as one diameter is lessened, the other is elongated, but this, according to Mr. Shaw, is never the case in rickets. In mollities, the bones have been fully developed

in rickets, their growth has been interfered with at an early period, and they have never attained their full size.

CLINICAL LECTURES

DELIVERED

At the Meath Hospital, or County of Dublin Infirmary, Session 1833-34.

BY PHILIP CRAMPTON, M.D., F.R.S.,
Senior Surgeon to the Meath Hospital, Surgeon-General to the Forces in Ireland, &c.

LECTURE I.

Introductory.—Qualifications of a Surgeon.

GENTLEMEN,—As senior medical officer of this institution, the duty (and it is a very grateful one) devolves on me of meeting you here this day and opening our Winter Course of Clinical Instruction. It is customary on such occasions to give some general views of the nature and scope of the medical profession, to describe the talents and attainments necessary for its successful cultivation, and, above all, to show the surpassing importance of clinical instruction, as a means of acquiring a practical knowledge of the healing art. For several years past I have abstained from entering on these topics, not because I undervalued their importance, but merely because they are so fully handled in distinct treatises, in the elementary works on medicine, or in the introductory lectures delivered at the different schools. On the present occasion, however, I am induced to revert to a topic which I have long left untouched, and, trite and exhausted as the subject is, I must say a few words respecting the qualifications which are considered as most essential for the study of medicine.

Here I must premise, that, in this country, we require much less from our students than our neighbours either in France or Germany. You will find that Professor Rothe (as quoted by Dr. Young) considers it "essential that the student of medicine should be intimately acquainted with all the languages, living and dead, from the Hebrew to the language of the gypsies; that before he enters on the study of anatomy and chemistry (which should occupy twenty years) he should be well versed in all the standard works, whether logical, metaphysical, moral, political, statistical, agricultural, mathematical, geographical, chronological, genealogical, (he forgot phrenological) heraldic, diplomatic, numismatic, and historical. Then Vogel only asks for talents and genius of the highest order, a penetrating intellect, a retentive memory, stability of judgment, rapidity of decision, immovable firmness, presence of mind, flexibility of temper, elegance of person and manners, and a profound knowledge of the secret recesses of the human heart." These, gentlemen, are "high claims and terrifying exactions." I will, however,

concede (and I hope you will consider the concession as sufficiently ample) that every person whom I address is possessed of every talent and every attainment contained in the German catalogue, yet if he be deficient in but one particular, which has been unaccountably omitted in the enumeration, I do not hesitate to say, that all his talents and attainments will be unavailing.

This would be a very disheartening statement, if the qualification which I require were one which (like most of the others which I have mentioned) must either be the gift of nature, or the result of an elaborate education; but the truth is, that it is perfectly attainable by every one, however humble his talents, or limited his education, if he be desirous of possessing it, and what is more, if you give me but this, I will take my chance for your possessing all the rest, and will ensure you at least a certain degree of success. Need I say that the faculty, to which I allude, is the humble one of *attention*. "By attention," says Locke, "the ideas which are presented to the mind are taken notice of, and as it were registered in the memory; it is the faculty which disposes a man to observe with the fixed intention of remembering." I apprehend, however, that Mr. Locke gave to the faculty of attention, if not a higher power than it actually possesses, at least a higher power than it usually exercises. In ordinary circumstances, attention is limited to the merely "taking notice of the ideas which are presented to the mind," while the act of "registering them in the memory" is another and a higher intellectual operation, which must in general be performed by an effort of the will. We must all have observed that our recollections are usually strong and durable, precisely in proportion to the interest which they excite in our minds, whether from their novelty, from the notion which we form of their importance, or from accidental association of ideas. Objects which interest us merely by their novelty, and which are not associated with ideas either of utility or pleasure, leave but a transitory impression on the mind—they "come like shadows" and "so depart." But if we are once persuaded, that, on a thorough acquaintance with those objects, depend the prosperity and happiness of our lives, they suddenly assume a very different degree of importance in our eyes, we observe each particular with the closest attention, and register it in our memories; and, by a remarkable law of our nature, this very exercise of attention generates an interest respecting the object, which, by a reflex operation, increases the attention an hundred fold, and renders that, which at first was perhaps but an irksome task, a delightful and all-engrossing pursuit.

This is the key to the explanation of that familiar but (at the first view) unaccountable fact, connected with the pursuits of men in the various departments of literature and of natural knowledge. One man begins the study

of Greek grammar, as a means of becoming acquainted with the language, and through the language with the philosophy and poetry of the early ages of Greece. He finds some difficulties in the Greek particles; he gives his undivided attention to the subject, every moment increases its importance in his eyes; adieu then to philosophy and poetry! he becomes a grammarian and nothing more, for the rest of his life. Another man is smitten with a love for astronomy, he begins by preparing the instruments necessary for its study; he fixes his whole attention on them and becomes enamoured with the occupation; he ends where he began, and is a caster and grinder of speculums as long as he exists. These indeed are extreme cases, they are instances of what may be called a morbid excitement, and a misdirection of the faculty of attention, in consequence of which the end is sacrificed to the means. They are useful, however, as illustrating the intensity of interest with which an object may be invested, without reference to its utility, merely by making it the subject of our undivided attention. If such things be true, and I apprehend they cannot be disputed, you will I think be disposed to admit that in estimating the respective values of the qualifications which are required from the student of medicine I have not overrated the faculty of attention. Of course you are not to consider this as an explanation of the mental phenomena connected with the faculty of attention, but as a mere statement of the facts conveyed in popular language; these are equally true, whether you consider the exercise of the faculty of attention as an individual power, or merely as the increased activity or excitement of each intellectual organ in the exercise of its respective function. The important truth which never can be too strongly impressed on the mind of the student is, that every faculty of the mind can by exercise acquire an increased degree of strength, and (if I may so speak) of dexterity.

Here then is the power. Let us see whether there be not in the very nature of the medical profession something which, perhaps more than in any other, calls on you for the exercise of this faculty. It was said of an eminent solicitor in this city, who cultivated several tastes as well as a taste for his profession, of which (by the way) he was suspected of being a little ashamed, that he was "a man of wit and pleasure on the town, who amused his leisure by being an attorney." Now however well this may succeed in the law, I am quite sure that it will not succeed in surgery, and for very obvious reasons. In the first place the offices of surgery cannot be performed by deputy, nor can the responsibility annexed to them be shared. In the second place they are in general performed in public, before a very critical and severe, but in the long run, a just tribunal. In this respect the case of surgery is different from that of medicine, and hence the different degrees of success which attend quacks or pre-

tenders to superior skill in these different departments of the healing art. It is too notorious to be denied that the highest medical reputations are made, and the highest prizes in medicine are daily carried off by men who not only do not pretend to any knowledge of the science of medicine, or, (to do them justice) of any other science, but who rest their claims to public confidence solely on their success, and to say the truth, when we consider that the very public to which they appeal are themselves the witnesses, and that the appeal is made to personal experience, it appears difficult to raise a doubt as to the soundness and sufficiency of the testimony.

Here then is a dilemma from the horns of which it seems hard to escape. We must admit, either, that in medicine the grossest ignorance can affect as much, if not more, than science and experience combined, or else, that patients are not competent to judge whether their diseases have been aggravated or cured by the treatment to which they have been subjected. Now strange as it may seem, the latter is the exact truth. The difficulty of coming to a right judgment as to the efficacy of any plan of medical treatment turns on this, that in all cases there are a great many influencing causes at work as well as the physician, and unless these causes admitted of being measured, or altogether excluded (which is plainly impossible) no estimate can be formed as to the effect of the mere medical treatment. If after two or three and twenty days of fever, when the patient seems at the last gasp, his eyes dim and blood-shot, his face of a dirty yellow, faintly tinted with pink over the cheek bones, his jaw fallen, his lips, tongue, and teeth, covered with a black crust, his hands waving tremulously over his bed-clothes, from which at intervals he seems desirous to pick off something, his breathing hurried, his pulse fluttering and almost extinct, if during this mortal struggle a warm and general perspiration breaks out, the pulse becomes full and equal, the eyes recover some "speculation," the tongue becomes moist, and every breast is filled with hope and thankfulness, who will venture to decide whether this great change has been wrought by the five grains of saturated ammonia, or the ten grains of musk, or the thirty drops of laudanum contained in the last draught that was swallowed, or by the mere inherent powers of the constitution unaided, or, it may be, obstructed by our interference?

There is an infinite deal of humour, as well as a great deal of truth in an observation of Ben Jonson's on this subject, as recorded by Lord Bacon in his apophthegms. Ben Jonson used to say (says Lord Bacon) that in sickness there were three things that were material—the physician, the patient, and the disease. If any two of these joined, then they have the victory, for "ne Hercules quidem contra duos." If the physician and the patient join, then down goes the disease, for the patient recovers. If the physician and the disease

join and pull the same way, then down goes the patient, (you see that rare Ben Jonson had no faith in homœopathie). If the patient and the disease join, then down goes the physician, for the patient dies, and the physician is discredited. Now as these coalitions take place in the very penetralia of the body, and as even the physician himself (and far less the public) can know nothing of them except by their results, it is quite plain that the respective claims of the parties to the merit of the cure, in any given case, can never be satisfactorily adjusted. In this uncertain state of things the public acts with liberality towards the physician. When the result is favourable the cure is ascribed to his remedies, and when unfavourable (unless in very flagrant cases indeed) the death is laid at the door of nature. No one, for example, blames the physician, and still less the empiric, when his patient dies of cholera, or typhus, or dropsy, or consumption; but should any case of the kind recover under his treatment, he is lauded to the skies. There is, no doubt, a great deal of justice, and perhaps of good nature; on the part of the public, in this method of adjusting the respective claims of nature and the physician; but, besides the justice and good nature of the public, there is another principle of the human mind which comes in aid of the physician, and still more of the empiric;—I mean that universal principle—the love of the marvellous. It is a delightful thing to have been the subject of an almost, if not quite, miraculous cure. What a subject for exciting interest and gratifying our self-love! How infinitely is our personal importance increased by having been cured in a moment, by some new and unaccountable process, of a disease that has baffled the whole Faculty for years! A man who has been cured of gout by colchicum, or of *tic douloureux* by carbonate of iron, is not to be mentioned on the same day, much less received into the same circle of society, with a man who has been cured by a magnet that raised three hundred pounds weight of iron! But this is as it should be. Human life would be but a dull drama if it dealt only in realities; and it would fare ill with the sufferer if hope were to close upon him when he had exhausted all the science of the Faculty. Let magnetism, animal and mineral,—let homœopathie and every other *pathic* have its day—and each will have it, whether the profession like it or not, whether they endeavour to extinguish it by their opposition or overlay it by their patronage—nothing in my mind can be less becoming the dignity of the profession than to stoop to either course. Let those whom we cannot help enjoy delusions, which at least are harmless; and if they beguile an hour of pain, or supply one beam of hope, they must, to a certain extent, be useful. Let the physician not incur the reproach which the lunatic of Argos applied to his too officious friends who cured him of a delightful delusion:—

“Pol, me occiditis, amici,
Non servastis, ait, cui sic extorta voluptas,
Et demptus per vim mentis gratissimus error.”

In an assembly of educated persons it cannot be necessary to protest against any conclusions being drawn in favour of quackery, because its foundations are proved to be laid deep in the principles of our nature, and because some fortunate empirics have made more money, than the Hunters or Baillies, the Pinels or Andrals. Quackery, in this respect, stands on precisely the same grounds as every other description of swindling; and a scientific physician would have as good a reason for burning his books and turning quack, with a magnet in one hand and a homœopathic pill in the other, as a merchant in good credit for withdrawing his capital from its investments in honourable commerce, and sinking it in a speculation for building a great gambling house. But if, from peculiar and unavoidable circumstances connected with the nature and treatment of internal disease, the physician has sometimes to contend with the empiric, let indolence or dishonesty draw no argument from this, unfavourable to the scientific pursuits of medicine. It is only by science and integrity combined, that the physician can successfully contend against empiricism. Let the weak, the ignorant, the credulous, and the hopeless, flock round the Moloch of quackery, and heap his altars with willing victims; there will still be enough of the learned, the virtuous, and the wise, to worship in the temple of Esculapius. But whatever fears or hopes may be entertained by the physician respecting the success of empiricism, to the surgeon, who must stand or fall on his own merits, the matter is nearly indifferent. All *his* proceedings are public; success cannot be pretended, or failure concealed. We hear every day of consumptions being cured by inhaling oxygen or carbonic acid, by washing the chest with vinegar and water, or with liquid blisters, by breathing the vapours of iodine or of turpentine, by magnetism, or by homœopathie, and we cannot doubt the truth of the statements, since they were made by the very persons who were cured or by their nearest friends. It is true, that they have not long survived their cure, but still their friends have the consolation of knowing that they died cured. Now, without venturing to assign limits to human credulity, I doubt if any one has as yet been convinced that a cataract has been extracted from his eye, or a stone from his bladder, by the application of the most powerful magnet; that a dislocation of the hip has been reduced by the metallic tractors, or a disunited fracture made firm by strychnine. One seldom hears a physician blamed for allowing his patient to die of cholera or typhus fever, yet a surgeon could scarcely bear up against the outcry which would be raised against him, if he permitted a man to bleed to death in his presence from an open artery, or to walk home with a frac-

ture of the neck of the thigh bone. As the surgeon, then, where the case proves successful, has the whole merit of the cure, he must be prepared, where it proves unfortunate, to bear the whole blame of the failure. There is, besides, this peculiar hardship in the situation of a young surgeon, that he is constantly put upon his trial, and brought into competition with men who are generally his superiors in reputation and experience; yet, should he prove to be mistaken in any point of practice, no allowance can be made for him on the score of inexperience, which will not be injurious to his reputation; and should he happen to be right, it is considered but as a matter of course. Now, although, from time immemorial, doctors have had a right "to differ," with this great advantage, that their disputes can never be settled, it is not so with surgeons. Between them it is a fracture or no fracture, aneurism or no aneurism, calculus or no calculus; and here, at least, the issue is of some importance, as it frequently involves nothing less than the life of the patient and the whole reputation of the surgeon.

I fear you will think that I have pressed this subject too hardly, and that I have lost time in labouring to prove a self-evident proposition; for who can suppose that surgery, any more than any other mechanical art, can come by inspiration? Nobody, I admit, can suppose it; and yet I find that too many act as if they supposed such a miracle would be wrought in their favour. Miracles are, however, very rare in these days, and to those who would depend on their luck, I would recommend the perusal of Miss Edgeworth's Tale of "Murad the Unlucky." But even at the hazard of being accounted tedious, I will mention a case to you; you are at liberty to suppose it an imaginary one, and to some of you it may appear improbable; but there are some, I trust, in this room, to whom it may convey information, if not admonition.

A young surgeon, with all those natural advantages of mind and manners which qualify a man to succeed in society, was appointed to a Dispensary which had lately been established in his native county. Surrounded by partial relatives and friends, and possessing qualities which entitled him to their esteem, it is not surprising that he soon acquired a very considerable reputation, and in a very few years became exclusively possessed of the general practice of a rich and populous neighbourhood. And here I may observe, that I can scarcely conceive a situation more enviable than that of a young and successful medical practitioner in the country. He must indeed be deficient in morals, manners, or education, if he is not the most popular man in the neighbourhood. Every moment of his time is either agreeably or usefully employed; respected and beloved by the poor, to whom he never appears but in the character of a benefactor, he passes through the country (whatever be its state of tumult and insubordination) by night or by day like

a being of a superior order; let destruction fall where it may, his property and person at least are held sacred. His occupation gives healthful exercise, not unmingled with pleasure; and if, in the course of his extensive rides through the country, he should chance to fall in with the hounds, why who is so welcome as the doctor? Health brings with it cheerfulness, and cheerfulness is the parent of kindness. Add to all this independence, with that most delightful of all feelings, which Mr. Edgeworth calls "the sense of success," and I think you have as many of the requisites of happiness as can well fall to the lot of humanity.

Well, our young friend possessed all these advantages, and he had besides the advantage of being received as a friend as well as a physician in the house of the lord of the manor, one of the most amiable and distinguished men in the country. His life passed on in this way for four or five years, every day adding to his reputation and happiness, until one fatal night, when he was called in haste to visit his patron and friend, who was suffering from a retention of urine. Having tried the usual means of relief in vain, he attempted to pass the catheter, but after two hours, spent in painful and ineffectual efforts, he is obliged to call for further assistance. Allow me here to explain the nature of the difficulty which he had to encounter, but was unable to overcome. Retention of urine in old persons is, nine times out of ten, caused by an enlargement of the middle lobe or portion of the prostate gland, which pushes up, in this way, into the cavity of the bladder, and pressing against the internal orifice of the urethra, prevents the escape of the urine. If the catheter be pressed backwards, or even upwards, its point bears against the projecting portion of the gland, and cannot, without perforating it, reach the cavity of the bladder. (Here Mr. C. exhibited a section of the bladder and urethra, with enlargement of the middle lobe of the prostate gland.) The point of the catheter was seen pressing against the projecting lobe, which prevented the instrument from passing into the bladder.

This difficulty gave time for the arrival of a young surgeon, who had been induced, by the extraordinary success of our friend, to establish himself in the same village—for observe, that there is not a village in Ireland, however small or remote, in which you will not find a competitor. "I fear," said the surgeon who had charge of the case, that this is a serious affair. I apprehend we shall be obliged to puncture the bladder, but try what you can do with the catheter." The young man, having ascertained the real state of the case by examining the prostate through the rectum, drew from his pocket a long and deeply curved catheter of the middle size, and having passed it up to the obstruction, depressed his hand, while at the same time he withdrew about an inch of the stilette, and the instrument instantly slipped over the obstruc-

tion into the bladder. In a few moments the patient was out of pain and out of danger. Need I describe the different feelings with which the two young aspirants for public favour turned towards their respective homes. The one, loaded with the praises and benedictions of a grateful family, springs upon his horse, which scarcely seems to touch the ground until he reached his home, where, in the bosom of his anxious family, he recounts every circumstance of his success, and indulges in bright anticipations of future fame and independence. The other, passing unheeded (it may be for the last time) through the silent hall, which lately rung with his welcome, returns with heavy steps to his cheerless home, ruminating as he goes with bitter but unavailing regret, on opportunities neglected and ruined hopes.

I wish I could say that this is an over-charged picture, and that no such mischance is likely to befall any man of ordinary education; but it is far otherwise. So boundless is the field of surgical practice, so various the complications of injury and of disease, that there is no man, however great may be his talents, or extensive his experience, who will not almost daily meet with cases which are new to him, and in the management of which there may be some nicety of practice which he has yet to learn. Is there a man who hears me, whatever may be his experience, who is not convinced in his inmost soul, that he is exposed to the dangers which I have described, every hour of his life? What, then, but the most inconceivable madness can induce a man to lose one moment of the time, which he can so usefully employ in laying up a store of experience, in folly and inattention? Can you persuade yourselves, that by conversing at the lower end of the ward, while some such trivial operation as the introduction of the catheter is going on at the other end, you are learning your profession? Do you expect to be impregnated with knowledge by the air of an hospital? Have you ever reflected on the consequences which must ensue to others as well as to yourselves, if you only begin to learn your art when you have to practise it as a profession?

It is painful, exceedingly painful to me, my young friends, to address you as I have this day, for the first time, in the language of admonition; but it is better to be admonished by me, than by bitter personal experience. What is it that brings me before you year after year, but the conviction, that the experience of no man can be commensurate with the demands on it. It is because I every day feel more and more the want of experience, that I gladly become your fellow student even, rather than your preceptor, feeling a deep conviction that the light which experience throws on our common path is to the full as useful a guide to me, as it is to you.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital, Nov. 9th, 1833.

LECTURE VII.

On a peculiar Injury of the Shoulder-joint.

GENTLEMEN,—The observations I am going now to address to you I have reserved for some time, with the hope that they might find a place in the first volume of the Transactions of the Royal College of Surgeons of London, when they had been rendered more perfect by the addition of proofs drawn from dissection. For this desideratum I have waited in vain, and as there is now a case in the hospital of the injury I shall attempt to describe, and which affords you an opportunity of estimating the description at its just value, and of judging of the correctness or inaccuracy of my opinions, I shall no longer defer giving them to you and to the public. It is possible that when attention is particularly drawn to the subject, an opportunity may be met with of ascertaining by dissection the exact nature of an accident which has caused me much anxiety at different times, and must, I conceive, have been a source of inconvenience even to others who may have been better qualified to form a judgment of the nature of these accidents than I am. As I wish on this point to be fully understood and fairly represented I will (if it be agreeable to the gentlemen who take notes for the weekly publications, and they think it worth their while) give them an opportunity of copying my own remarks on the subject, in fact, the very paper I now hold in my hand. Mr. Foote will remain here to read it for copying, if required by any one of those to whom I have alluded. I have no interest in any journal, save that which arises from civility, and there is an old saying, that civility begets civility. The first case I shall adduce is that of Louisa Chapman, eleven years of age, who fell on the shoulder on the 8th of October last; and is under the care of Mr. Lynn.

This child's shoulder is, as Mr. White aptly calls it, out of drawing; there is a considerable prominence on the inside of the anterior part, beneath the coracoid and acromion processes and in the situation of the small tuberosity of the humerus. This projection is so manifest as to be seen at a distance, and when examined it might be mistaken for the head of the humerus displaced into this situation, and constituting a partial dislocation if it were not for two circumstances. 1st. That it is not the whole of the head of the humerus which is felt projecting internally, neither is it round, but on the contrary, it is distinctly a rough and irregular protuberance of bone. 2ndly. That the greater part of the

round head of the humerus may be felt in the glenoid cavity.

If the thumb or fore-finger of the left hand be placed on the internal protuberance of bone, whilst the elbow is rotated by the right, the protuberant portion of the humerus is found to obey the motions given to the elbow in the clearest possible manner. If the fore-finger be carried outwards and placed upon that part of the joint in which the external part of the head of the humerus ought to be placed in its normal state, it will be found there, and moving most distinctly under the finger when the elbow is rotated. The arm can be elevated and the hand placed on the top of the head. There is no peculiar or decisive sensation communicated to the fingers when pressed into the axilla, and the elbow can be brought close to the side with ease although it tends a little backwards. If the point at the fore-finger be placed immediately below the middle of the acromion process, it sinks into a hollow between the protuberant point of bone and the articulating part of the humerus which moves in the glenoid cavity; and if the two shoulders are compared, the greater width of the injured one is apparent. What is the injury? Dissection has not yet explained it, but I believe that it is a longitudinal split of the humerus. The accident always happens in consequence of a fall on the point of the shoulder, in which the head of the humerus covered by its investing parts first meets the ground and receives the shock. It occurs, then, from direct violence committed to the part. In some cases there is an indistinct crepitus, and in one case I shall mention the whole head of the bone was dislocated as well as split. I believe that the split separates the small tuberosity with more or less of the head, and extends in the direction of the bicipital groove, and I suspect that the tendon of the pectoralis major in front, and those of the latissimus dorsi and teres major behind, prevent displacement by acting in the manner of a hinge. The crepitus is not always distinct, especially in young persons, on account of the cancellated structure of the bone being soft, and its interstices being filled by medullary matter. The arm is shorter, in this instance, when measured from the acromion to the olecranon, by half an inch.

Mr. Lynn differs in opinion with me as to the nature of the injury, and states that it is an accident he has never seen before during the nearly sixty years he has attended this hospital as student and surgeon. You may judge, therefore, of the importance of surveying it well. No man has a more affectionate regard, nor reverence, for Mr. Lynn than I have, no one more highly appreciates his long and valuable professional services than I do; and, some thirty-one years hence, if I ever live to that time, and to equal his present age, I shall be glad to be as good a surgeon and as good a man. Still we may differ a little now, with advantage to me at all events. There is always

something to be gained by friendly collision with a man of great experience, even if it should be only the lesson that the greatest value of experience and the observations to be drawn from it is obtained, when they are directed to particular objects, and not embracing everything generally. There have been, I believe, two similar cases in this hospital in the course of the last year. One was of a brewer's drayman in Matthew's ward, about forty years of age who fell on his right shoulder, and suffered the injury I have described, but which I did not then so well understand as at present. I requested the opinions of Mr. Lynn, Sir A. Carlisle, and Mr. White on this case. Mr. White then said as now, that it was out of drawing, and Mr. Lynn said the man would get well and have a good useful shoulder, which he had ultimately, although the projection remained. This case Mr. Lynn recollects, but he does not think that it was quite the same as that of this child.

The second case was of a boy who lay in the bed nearest the door of the opposite ward. The late Mr. Alcock, who was in the habit of attending frequently at this hospital, paid particular attention to him, and the history of the case was taken at length, but some gentleman took a fancy to the book and stole it. This boy also had good use of the arm, although the protuberance was still greater than in the brewer's man. The third case I shall adduce was that of Colonel Yorke, now secretary to the Governor of Jamaica, Lord Mulgrave, about thirty-five years of age. He was thrown from his horse two years ago in Hyde-park, and pitched on his left shoulder. I did not see him until two hours after the accident, and the shoulder was a little swelled, but not sufficiently so to prevent an accurate examination. The only symptoms differing from what you may see in this child were a little more protuberance on the inside, and a crepitus on rotating the elbow, which, when present, was sufficiently distinct but was not always observable. I made several examinations before I was quite satisfied of the nature of the injury, and the late M. Delpach of Montpellier having done me the favour to dine with me some few days after it happened, I mentioned it to him, and as he had never seen a case of the kind and wished particularly to verify it, I took him to Colonel Yorke's, and showed it to him. He was not only satisfied but delighted with it, and expressed to Colonel Yorke his fullest acquiescence in the opinion I had given of the nature of the injury. The treatment consisted of a padded back board, and two broad soft padded straps of chamois leather, which went under the arms and fastened to four brass pins in the board behind, there being several holes in the straps to admit of these being drawn as tight as might be required or could be borne. One of these straps pressed upon the prominent piece of bone. The elbow was supported, carried forwards, and fastened close to his side; and, after a time, passive

motion was resorted to, and he recovered the use of his arm and left off his bandages at the end of ten weeks, and suffers now, I believe, no inconvenience from the accident, although there is still a certain degree of prominence remaining. The effect of the treatment was to bring the split portions of bone nearer to each other, as well as to consolidate them. He has promised me his shoulder when he dies, but demurs about dying before me, and I hope this notice of his case may induce some surgeon whenever he does die, to ask permission to examine his shoulder. The report will be interesting even at the distant period to which I hope it may be deferred.

The last case I shall mention came under the observation of several of you, although a private patient, because I brought him into this theatre for the convenience of the pulleys. Mr. Perry, jun. of Perry's Place, Oxford-street, about eighteen years of age, fell on the point of the shoulder, at Amersham, and was supposed, by Mr. Tennant his surgeon, to have dislocated the head of the humerus, which he duly reduced. It did not, however, remain in its situation, and was I believe again replaced. Still there was something wrong about it, and at the end of three weeks his friends brought the young gentleman to me. On examination, I found the elbow was carried very far backwards, and the head of the os humeri proportionably forwards, and apparently dislocated in that position; but the prominent part was not round like the head of the bone, and did not give that sensation to the touch; on the contrary, it felt, to my ideas, as if the head of the bone was split as well as dislocated. I had the pulleys prepared here, and brought him down; the extension was made and kept up for nearly an hour, until, in fact, he could bear it no longer, and all the bandages had slipped. The bone moved considerably from its original situation on the inside of the glenoid cavity under the extension; but it did not long remain in that position when the extending power was removed. Mr. Tennant had done, in fact, as much as I had, and with the same success. As soon as the skin of the arm, which had been ruffled by the bandages, was sound, I once more submitted him to the pulleys, exerting even a greater power upon him whilst in a state of exhaustion from loss of blood and from the effects of tartar emetic. I brought the whole head of the bone below the level of the glenoid cavity, but could not entirely remove the prominence. When taken out of the pulleys, the outer portion of the head of the humerus appeared to be in the glenoid cavity, but the inner and greater part of it was internal to it. The arm assumed, however, more of its natural appearance; the elbow was in its proper direction, and could be readily pressed or struck against the ribs. In order to prevent another escape of the bone, I put on the same back-board as I had used in Colonel Yorke's case, and treated it altogether in a similar way. He recovered

at the end of several weeks, and went into the country with a good and very useful arm, promising that if he should happen to die before me and had time to think of it in his will, he would leave me the examination of his shoulder, or to some one else if I were dead. He departed this life, however, on the 25th of last November, without thinking any more of the matter, and his friends, who promised as well as himself, were too unhappy to recollect such a circumstance. I regret it very much, but was not aware of his death until long after he had been buried.

In this case the capsular ligament of the shoulder joint must have been torn; and I believe the whole of the head of the humerus was dislocated as well as split, which may be a reason why it so readily became displaced, a second and even a third time; for there is no reason to doubt its having been duly reduced by Mr. Tennant, at Amersham, although he could not restore the protuberant part to its place for the reasons I have assigned. The friends of the young gentleman were, and remained, exceedingly dissatisfied with him until they saw the difficulties I had to encounter here, when they began to suspect he did not deserve it; and when I told them there was no record in print describing the nature of the accident, they declared themselves, as I assured them they ought to be, contented.

I have seen a case in which the humerus was broken and the head alone remained in the glenoid cavity, but it did not resemble the cases here described; and I cannot, after much consideration, take any other view of the nature of the injury than that I have given you. Nothing will effectually clear up the difficulty and uncertainty which envelope this subject but a dissection of the parts concerned in it; and I can only hope that the remarks I have made will draw more attention to it, and lead to positive results. I shall consider the surgeon fortunate who can add the desired information to our existing knowledge of the injuries affecting the shoulder-joint; and shall be very much obliged and gratified if he will send me a drawing and an account of the appearances of the parts on dissection.

THE DISCOVERIES OF DR. RICORD OF THE HÔPITAL DES VENERIENS OF PARIS, RESPECTING THE VENE- REAL DISEASE,

Claimed in a Letter to the Editor.

BY WILLIAM WALLACE, M.D., EDIN., M.R.S.A.,
*Surgeon to the Dublin Infirmary for Diseases
of the Skin, including Venereal Diseases,
and to the Jervis Street Dispensary; Au-
thor of a Treatise on the Venereal Disease
and its Varieties, &c. &c.*

WHEN I consider your character for liberal impartiality, I have little doubt of your as-

sistance on the subject of the following letter. Therefore, although personally a stranger, I do not hesitate to address this communication to you, and to request that you will be pleased to give it a place in the pages of your very valuable Journal.

Having devoted for many years a great deal of attention to the investigation of the venereal disease, I observed, naturally with much interest, the papers in Nos. 90 and 91 of the London Medical and Surgical Journal, which give an account of certain researches lately made on this disease by Dr. Ricord of the Hôpital des Vénériens of Paris. Indeed, as soon as I saw the title of these papers, I entered on their perusal, and I trust I shall be excused for observing in this place, that, when I had read them, I could not avoid immediately exclaiming, here is a confirmation of many of my facts and conclusions, yea, of those which have met the largest share of opposition! here is a proof of the care with which I have considered the subject of the venereal disease; for I do not find a single assertion in these papers which I have not investigated, or scarcely a fact which has not been either published by me, or which may not be directly inferred from those which I have published!

Has Dr. Ricord, said I, been led by my work, or by any knowledge of my views, to make these researches? or have they been instituted by him without any knowledge of my labours? These are questions which, of course, I cannot answer, but you and the profession will judge when you are made acquainted with the coincidence of our facts and opinions, and when you are informed that my views have been promulgated, for many years, in my clinical lectures, that two years have elapsed since my work on the Venereal Disease was put to press, and that it was published many months before Dr. Ricord's papers were read to the Royal Academy of Medicine. Yet, in these papers, no mention whatever is made of my name, although it may be fairly concluded that my work was then known in Paris by the ordinary course of publication. It is a curious circumstance, and of some importance on the present occasion, that during a visit paid by me to London, in the end of the summer 1831, that is a few months before Dr. Ricord (according to his own admission) commenced his experiments, I freely promulgated my opinions and experiments among a great number of practitioners, lecturers, and students, among whom there were several foreigners, and, at the same time, exhibited a vast collection of drawings of the cases of the disease upon which I had founded my opinions.

In short, were I not fearful of making this communication too long, it would be most easy, by extracting parallel passages from Dr. R.'s papers and my publication, to remove all doubt from the mind of every impartial inquirer, that this gentleman has been long since anticipated by me. I feel, however, that I must be content for the present with classing

under certain heads the more important and striking of Dr. Ricord's facts and views, and with referring to the pages of my work, in which the same have been previously published. Nor do I entertain a doubt, that this will be quite sufficient to induce such of the profession as are interested in the progress of our knowledge respecting this important disease, to refer to the original writings, and make for themselves a comparison between Dr. Ricord's inquiries and mine.

Contagious nature of the Venereal Disease.

Dr. Ricord maintains, in opposition to many of his countrymen, that the venereal disease is contagious; an opinion which few in these islands will deny, although it is an opinion which has been so opposed by many able men on the continent, that I felt myself called upon to endeavour to set it to rest in the first chapter of my work, in which I inquire, "*Are venereal diseases produced by a specific cause or morbid poison? or do they arise from common causes of irritation?*"

Characteristic form of the Venereal Disease.

Dr. Ricord maintains from his experiments that a "characteristic pustule," or one which follows a regular and determined course, is produced by the contact of the venereal poison, and can be produced by no other means. The same opinions are advanced and proved at pages 57, 8, 9, and 60, as well as in several other parts of my work. To this pustule and the ulcer in which it terminates, I have given, for the reasons advanced at page 57, the name of "*regular primary syphilis.*"

Description of the characteristic form of the Venereal Disease.

Dr. Ricord and his translator have occupied a very large portion of their papers in giving a description of the "characteristic pustule," as it occurs on the skin; but its history and that of the *subsequent ulcer* as minutely traced by me, not only as they occur on the skin, but also as they appear on several other parts. See page 65 and following pages of my work.

Inoculation with the Venereal Poison.

Dr. Ricord maintains, that an individual affected with a lesion of a syphilitic nature is still susceptible of receiving another from inoculation, and that the danger of the disease is not thereby increased. See several parts of my work, as at pages 71, 2, 3. The knowledge of these facts induced Dr. R. to inoculate persons already labouring under the disease, in the hope of adding to our knowledge of its diagnosis, &c. See pages 82, 355, &c. of my work.

The matter of Bubo will produce the characteristic form of the Venereal Disease.

Dr. Ricord has proved by experiment that the matter of bubo possesses the power of pro-

ducing by inoculation the characteristic pustule. The same truth, which Dr. R. styles "one of the first importance," has been proved by my experiments. See page 355. There exists, however, this difference between us. Dr. R. affirms that he scarcely ever failed to produce the characteristic pustule by inoculation with the matter of bubo, whereas I have found this result to follow comparatively seldom. There are, however, certain circumstances, which may explain these differences, and which any one who reads Dr. R.'s papers and my work cannot fail to observe.

Characteristic Pustule produced by the matter of Gonorrhœa, &c.

On three occasions, Dr. R. produced the characteristic pustule by the inoculation of matter of blennorrhagia, or, in my language, of catarrhal or gonorrhœal primary syphilis, taken from the urethra of "males in whom there was not the least external excoriation, nor any visible ulcer of the urethra." It is, however, to be observed that the conclusions which Dr. R. has drawn from these experiments are not the same as those deduced by me. Indeed, his conclusions are not quite clear or decided. It seems, however, from the statement of his translator, that he is of opinion that blennorrhagia will not produce the characteristic pustule, unless the discharge be accompanied by ulceration; and hypothesis on this subject leads him to believe that ulcers existed in the cases above quoted, although he admits that of this there was not a shadow of proof. See pages 56, 231, &c. &c.

Influence of habit in determining the nature of the disease produced by inoculation from the "Characteristic Pustule."

Dr. Ricord, if I understand him right, maintains from his experiments, that the matter of the characteristic pustule will produce in certain habits the serpiginous ulcer; a most important fact in relation to the hypothesis of a plurality of venereal poisons, and similar to those proclaimed in my work from page 13 to page 40, and at page 210.

Secondary effects of Blennorrhagia.

Dr. Ricord admits, as a consequence of blennorrhagia, alterations of the bony and mucous system, and pustules on the surface of the skin. P. 56, &c.

Diagnosis of Blennorrhagia and of the "Characteristic Pustule."

It is the conclusion of Dr. R., that there exist no symptoms by which virulent blennorrhagia can be distinguished from certain non-virulent discharges. See my work, pages 58 and 233 and following. On the other hand, it is maintained, at least by the translator of Dr. R.'s paper, that a diagnosis of the characteristic pustule may be obtained from a consideration of all its phenomena; and that

the characteristic ulcer may occur without being preceded by a pustule, if the virus be applied to a surface which has been deprived of its cuticle. See pages 81, 84, and following of my work.

Length of time that the contagious quality of the "Characteristic Pustule" continues, &c.

Dr. Ricord mentions the following opinions, which will be found embodied in the views respecting ulceration, &c., given from page 49 to page 55 of my work, viz., That the contagious quality of the "characteristic pustule" may persist after the process of healing has commenced, and even until the ulcer is perfectly healed; that the formation of bubo requires certain relations between the surface of the "characteristic pustule" and the absorbent orifices; and that no contamination results from the "characteristic pustule" in its primitive state.

Influence of the Nitrate of Silver in arresting the progress of the "Characteristic Pustule."

It is communicated that, if the nitrate of silver be properly applied during any of the four first days of the progress of the "characteristic pustule," it will be arrested in its course and healed; a position particularly enforced by me from page 92 to page 99, inclusive.

I fear I must, for the present, end here, lest I should tire you by further particulars. I trust, however, I have said enough to accomplish the object of this communication; that is, as before remarked, to induce such persons as are interested in the history of the venereal disease (and few subjects are of more general interest or importance to medical practitioners), to compare my work with the writings of Dr. Ricord. Nor have I, I repeat, any doubt that whoever shall make this comparison will admit that I have not only anticipated this practitioner, but also that I have published a host of facts relating to the very object of his paper, viz., the diagnosis, the progress, and the propagation of the "characteristic pustule," and of blennorrhagia, which he has entirely overlooked. I am also convinced, that whoever shall make this comparison will no longer view Dr. Ricord's researches in any other light than as confirming my facts and conclusions; and moreover, will admit, that if Dr. Ricord has not been led to his investigations by the perusal of my work, or by the oral communication of my views, his having observed the same facts, and arrived at the same conclusions with me, is a powerful argument in support of both our researches, so far as they agree. But, before concluding, I must observe, that, if I can rely on the testimony of my senses, Dr. R. has fallen into several errors, and particularly in respect to the contagious quality of certain forms of the disease. Upon this subject, however, I cannot at present enter, as well because

I should be thereby deviating from the express object of this letter, as because, if I entered on the refutation of his opinions, I should be compelled, in several points, to anticipate considerations which will have their place in the forthcoming volume of my work.

It may, perhaps, be supposed by some, that originality is not claimed by Dr. Ricord, for he says, "doubtless in this paper *all* will not be new, for I have rather observed the patient—I have rather sought for the results of experiment—than for the opinion of others." But, surely, the whole tenor of Dr. Ricord's remarks implies, notwithstanding the *saving* sentence just quoted, that his facts and conclusions are, if not "*all*," principally new. As a proof of this, let me refer to that part of his paper, in which he lauds *his* discovery of the contagious nature of the matter of *hubo*; a discovery resulting from experiments made known at page 355 of my work. In fact, any one who reads Dr. R.'s papers, if he has not read my work, must give him the merit of having first ascertained the facts which he puts forward. The importance of deriving our facts from our observation of nature, before we make them the basis of our reasoning, I am not likely to deny. But will this necessity justify an author to bring forwards, as his own, such as have been ascertained by another—although of another country. If this be permitted, there is an end to one of the most powerful motives to investigation. "*Render to Cæsar the things that are Cæsar's*" should be the sacred motto of every author anxious for the advancement of science.

Great Denmark-street, Rutland-square.

ANATOMICAL NOTES.

DISCOVERY OF THE TRUE DISTRIBUTION OF THE OBTURATOR NERVE.

BY ALEX. THOMSON, M.B., OF ST. JOHN'S CAMB.

(Continued from page 463.)

Obturator Nerve, traced in its whole course.

14th Subject, a Male.—On emerging from the *psaos* muscle it passes forwards across and in contact with the ilio-lumbar artery, between it and the fork made by the division of the external and internal iliac arteries, from thence proceeds forwards, descending slightly outwards across the middle of the anterior edge of the base of the sacrum, and from thence in a nearly direct line to the posterior point of the sacral canal, being however slightly convexly bent outwards to correspond to the perpendicular internal surface of the ilium, interiorly of the fascia pelvica, immediately above the normal obturator artery, which is above the corresponding vein in this case. At its origin, or immediately below the point of reception of its third root, and coming apparently from that root, it sends off a delicate filament,

one-third of a line in diameter, which passes obliquely outwards, and downwards into the *psaos* muscle, and may be traced branching in the same to nearly as far as the femoral arch, and giving numerous twigs to that muscle in its course. Half an inch further down it sends off backwards, downwards, and outwards, another very slender twig, which, after a descending course of three-quarters of an inch, plunges into the anterior part of the upper surface of the ilio-sacral symphysis. These, when opposite to the middle of the ilio-pectineal line it sends off two distinct twigs, one posterior for the internal obturator, another, one line before the last, for the hip-joint. The former is about one-third of a line in diameter, pierces the pelvic fascia, and descends exteriorly to it and to the levator ani, to be lost in the obturator internus. The latter is about one-half a line in diameter, pierces also the pelvic fascia, ascends obliquely upwards and forwards exteriorly to it, and, after a course of about half an inch, again pierces the same fascia to arrive in the iliac fossa, by winding over the linea ilio-pectinea, then turns forwards, and descends in that direction in a groove, formed by the insertion of the *psaos parvus* tendon to the ilio-pectineal line and ilio-pectineal eminence, remains in this groove running along the ilio-pectineal eminence, until it arrives at its anterior point, then curves downwards, backwards, and slightly outwards, and divides into numerous twigs, that pierce the capsular ligament, to be again subdivided and distributed on the synovial membrane of the hip-joint. At the moment of entering the groove on the iliac fossa, this branch sends off outwards and downwards two very distinct twigs, which diverge but slightly from each other, proceeding towards the notch made by the ilio-pectineal eminence, and the lower anterior spine of the ilium, dividing midway between their origin and the anterior edge of the notch into numerous twigs, of which several pierce into the adjacent parts of the iliac fossa, and the remainder are distributed to the synovial membrane of the bursa lining this notch, and to plunge here again into the outer parts of the anterior surface of the capsule of the hip-joint, to be there again redivided and distributed to its synovial membrane.

Arrived at the obturator canal, the main nerve traverses it above the artery and vein, passes downwards behind the fascia, separating the pectineus from the obturator vessels, and divides into two series opposite to the fascial re-union, separating the adductor brevis and obturator externus. When at the outer orifice of the obturator canal it sends off from the inner edge of its surface a branch of about one-third of a line in a diameter, which curves outwards, and after a descending course backwards of about half an inch, divides into two principal twigs, a superior and inferior; the superior enters at once into the anterior cotyloid notch, behind the cotyloid crucial ligaments, to be distributed to the cotyloid twigs of the obturator artery,

to the fatty red cellular tissue, lining the rough fossa of the cotyloid cavity, to the synovial membrane of that tissue, to the synovial membrane of the round ligament, through which some of its twiglets may be traced passing to the head of the thigh-bone. The inferior twig of the articulari-femoral branch passes backwards and outwards and slightly downwards, behind the head of the femur, and when opposite to the anterior edge of the inferior part of the cotyloid crucial ligaments, divides into numerous twiglets, that pierce the inferior, interior, posterior part of the capsular ligaments, and are then distributed on the femorali-capsular synovial membrane. The femorali-capsular branch also, near its origin from the main nerve, sends a small twig into the outer bony wall of the obturator canal, that is, into the ilium. The main nerve now sends numerous filaments into every one of the branches of the obturator artery and vein, and two muscular branches, one directly after its exit from the obturator canal, that plunges, after passing over the anterior face of the obturator artery and vein, to gain their inner edge, through the obturator aponeurosis, and is lost in the obturator externus muscle. The other is about two-fifths of a line in diameter, comes off from the inner edge of the nerve about half an inch lower down, curves round inwards, downwards, and backwards, above the fascia, separating the adductor brevis and magnus from the obturator externus muscle, and is also, after a course of an inch and a half, divided into numerous twigs, that plunge into the obturator externus muscle.

(To be continued.)

NOTE ON THE TREATMENT OF BLUE CHOLERA.

BY ALEX. THOMSON, M.B. OF ST. JOHN'S, CAMB.

I WAS sent last year into the villages of Noudon l'Abbesse and Festieuse, in the Department of the Aisne, each containing about 850 inhabitants. I had more than seventy cases of blue cholera, of the most severe character, (several patients having died six and eight hours after the attack,) and from three to four hundred cases of cholérine, or incipient cholera. I lost less than one-third of those who had true blue cholera, although it was combined with a disease called *nette Picarde*, in itself excessively fatal, as is attested by certificates given me by the maire and the pre-fets of the department.

My treatment was exceedingly simple:—

1st. Perfect repose, to such an extent that I did not permit the patient to get up, or be moved on any account, not even for the wants of nature.

2nd. The most rigorous abstinence from fluids as well as solids.

3rd. The terrible thirst was quenched by gargling the mouth with the coldest water procurable; and it is worthy of remark, that

VOL. IV.

when the water was swallowed accidentally, or from negligence, or from cunning of the patient, the cramps and the vomiting never failed of re-appearing, even after reaction had commenced.

4th. General warmth obtained by hot bricks and blankets.

5th. General urtication of the whole of the trunk and extremities every five minutes until the commencement of re-action. In the absence of nettles (*urtica piluifera*) frictions at equal intervals, of the same parts, with a liniment, containing one part of liquor ammoniac and seven parts of sweet oil, were employed with success.

6th. Twenty-five grains of subcarbonate of magnesia, and more rarely an equal dose of bicarbonate of soda, in an ounce of syrup of gum, with a teaspoonful of brandy, repeated a second time after the lapse of half an hour in some rare cases, never failed to stop the vomiting with a magical rapidity.

7th. A clyster, containing an ounce of starch, twenty-five drops of laudanum, and eight ounces of water, rarely failed in arresting the diarrhoea, although, in a few cases, it was necessary to repeat the same two or three times at the distance of half an hour, in order to attain this object.

8th. In extreme cases, when re-action could not be obtained by the preceding means combined, it was necessary to add to the above-mentioned clyster, twenty, thirty, and sometimes even forty drops of spirits of turpentine, and to administer by the mouth six or eight ounces of generous branly punch.

Those of my patients, who died, sank rather under the negligence, and from the ignorance and fear, of their relatives, than under the effects of the disease. I found it indispensable to have a nurse for each patient, and to visit them myself at least three times in the twenty-four hours.

November 7th, 1833.

CONTINUATION OF M. ALIBERT ON THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

Late Senior Surgeon to the Royal Metropolitan Infirmary for Children, &c.

ARTICLE VI.

Of the Results furnished by a Chemical Analysis of the Crusty and Furfuraceous Substances which are produced by the different Species of Teigne.

M. GALLOT has investigated the nature of these productions, assisted by M. Thenard. In these crusts, carefully examined, coagulated albumen

KK

predominated; a sixth only was soluble by water, and gelatine and phosphate of lime were found to be present. It was necessary to extend these investigations, in order to render them of more medicinal importance, consequently after M. Vauquelin had proceeded to comparative inquiries, respecting the crusts and scabs proceeding from three different kinds of scald heads, viz. the favous, granulated, and furfuraceous. This celebrated man has executed this interesting work in union with M. Cabal, one of his most zealous pupils and co-operators. I think it superfluous to detail here their proceedings, in order to arrive at a perfect knowledge of their produce. I shall confine myself with saying, that the favous crusts are more albuminous than gelatinous, that the furfuraceous, on the contrary, are more gelatinous than albuminous, that the granulated are all gelatinous. It is to be regretted that we have not been able to join to this analytical inquiry those which the amianthous and mucous forms must necessarily offer in their turn, but as the matter of the desquamations, furnished by these two, is so difficult to collect, we have been obliged to defer the examination.

ARTICLE VII.

Opinions on the Methods employed for the cure of the Teignes.

WHEN we consult authors we generally perceive them pretending to cure these diseases before they know well what they are, and the vast number of recipes they have succeeded in gathering together surprises us, but this abundance of reputed curatives attests rather our indigence than resources, in short, the more remedies there are tried for any affection, the greater reason we have to think there have been fruitless attempts; it is because certain medicines have not succeeded, that numerous inquiries have been made to find others. What has happened relative to the cure? Nothing has been decided on. Empiric for-

mule have been heaped together, and this interesting part of cutaneous pathology has fallen into the hands of quacks. We have already remarked that the different eruptions of the scalp have a manifest tendency to the preservation of different parts of the animal economy. Before, therefore, curative methods are employed, it is necessary to examine whether or not it will be better to cure them, as it cannot be denied that too premature a cure sometime subjects the individuals attacked with it to serious inconvenience. I attended a girl, aged 14, who had intolerable pains in the stomach, accompanied with uterine catarrh, from having been delivered too quickly from this exanthema. A woman was brought to the Hospital St. Louis, whose forehead was covered with favous pimples, and who had lost her sight through violent repulsives being applied on her head. Has it not been observed in some cases, that the virus of the teigne displays itself in the joints, and even brings on the spina ventosa, or scrofulous phthisis? At other times the patient falls into hectic fever, the irritation is transferred to the glands of the mesentery, and a mortal diarrhoea occurs. Still the severe suffering, experienced in many cases, does not allow us to be idle. The state of the glands of the lymphatic system and of the cellular structure, which I have particularly remarked in the favous, does not permit us to leave the cure to nature; and I must say, that though the cure of the eruptions in question is prejudicial to the animal economy, when it is undertaken in a hasty and inconsiderate manner, it is right to attempt it by cautious medicinal treatment. It is time to disengage the treatment of the different scald heads from the nonsense of blind quackery.

ARTICLE VIII.

Of the Internal Treatment for the cure of the Teignes.

THE judicious or successful treatment

can never be purely local ; a substitute for the discharge from the scalp must be found and put into use before local sedative applications can be used safely. Our practice in the Hospital St. Louis confirms what we have advanced. It is remarked, as a first principle, that children subject to nasal hæmorrhage or fœtid urine, are less subject to the disease, or at least get rid of it easier, than those in whom no such evacuations take place. Individuals whose cases are severe are hardly ever afflicted with the catarrh of the mucous membrane of the nostrils, or even other affections common to children. The necessity of an internal treatment has been perfectly admitted by Hippocrates and his disciples, though his supposed remedies are inert ; yet internal treatment is chiefly relied on. Mild purgatives and a system of diet and regimen constitute, (modified according to circumstances,) the internal treatment. The strength should not be too much exhausted by internal medicines, or the external disease too suddenly checked by the use of sedative applications.

ARTICLE IX.

Of the External Treatment employed for the cure of the Teignes.—Local Applications.

THE prescriptions for these have been multiplied astonishingly. Each author appears to propose a remedy of his own invention. They have all by turns recommended caustic, or sharp and narcotic substances. The celebrated plaister, employed in the time of Ambrose Paré, was composed of hellebore, orpiment, litharge, vitriol, alum, quick lime, ointment of mercury, grease, and the juice of plants ! and of later, and up to modern days, has been more or less used in our hospitals. No one is ignorant of this preparation ; it consists in spreading on cloth a preparation composed of rye flour, strong vinegar, and pitch, after having softened and caused the crusts to fall off by the aid of poultices, the plaister is put on and left to dry

on the scalp ; three days after it is torn off with violence, and the application renewed. This cruel operation is continued for several months, and each dressing pulls away a number of hairs ; neither the suffering nor screams of the children, during the tearing off of the plaister, has induced them to discontinue this extraordinary method. The empirics employed for it do not even know what kind of teigne they have to contend with, and have no other guide but a blind road from which they will not depart. More people with scald heads repair to the Hospital St. Louis than any where in Europe, and for a long time this method was used. I detail with impartial exactness the facts I have carefully collected with M. Gallot:—1st. Six months at least were necessary for the cure of children, and few, very few, were cured in that time. 2nd. A tolerably large number we succeeded in curing in from nine to twelve months. 3rd. Several were cured in the course of the second year. 4th. Three years were necessary for those who had this disease very obstinately. 5th. We have seen it continue after this time. 6th. The cure is not always radical, and several who have relapsed have required a new treatment. 7th. Some children have had serious illnesses after the cure of the scald head from the proceeding above named. We have seen three remain languishing and in ill health, after the extirpation of the disease by means of the cap*.

* Monsieur A. condemns in terms of strong indignation this most abominable infliction, and shows its inefficacy as well as its mischief. He questions the superiority of extraction of the hair by forceps. He equally condemns cauterisation, or the use of blisters, but has seen the use of lime often successful, apparently by destroying the hair and cuticle ; hardly, we should imagine, without much pain and suffering on the part of the patient, and destruction of at least the surface of the cutis. He mentions a variety of supposed remedies, well known in this country, such as the ointments of white precipitate of mercury and of oxide of manganese, acetate of copper in solution, poultices of bread, and solution of oxy-muriate of mercury, all productive of great irritation and mischief, and none of a cure,

Reviews.

Description of an Apparatus intended to facilitate the treatment of Fractures of the Lower Extremity. By T. M. GREENHOW, M.R.C.S.

THERE are perhaps few professions in which mechanical skill and contrivance are of more value than our own. To the practical surgeon it is frequently of great use. In the reduction or steadying of a dislocated or fractured limb, and in the simple process of arresting hæmorrhage by the screw of the tourniquet, its resources are equally available. The screw is at once the steadiest and safest contrivance used, and Mr. Greenhow has applied it with great effect in his excellent apparatus.

"The first part of the apparatus to be described is a stand, to be placed upon the bed for the purpose of suspending the leg in an easy sling. This is formed of iron, and is of an oblong figure, with an upright pole at each corner; a moveable framework, consisting also of four upright extremities, connected by a longitudinal beam at bottom, and having slides at each corner, which play upon the four poles of the lower part of the stand; it admits of being raised or depressed as occasion may require, by means of a perpendicular screw placed in the centre of the longitudinal beam. In this way the height may be varied from twelve to eighteen inches. The poles are furnished with hooks at the top, between which is suspended a cross strap at each end of the stand, and on these straps is supported that part of the apparatus on which the fractured extremity is to be placed. This sling, though sufficiently strong, is neat and light in its appearance, and will stand steadily upon the bed, provided the lower end be supported by a string attached to the bed-poles.

"The remainder of the apparatus may be considered as a species of splint. The knee is received into a deep hollow, where the part appropriated to the leg is united to that which is fitted to the thigh at an angle of about 35 degrees. This forms a permanent flexion of the knee-joint, at that angle which I have found

most comfortable to the patient, which relaxes the largest number of great muscles, and which enables it to be made an undeviating fixed point in performing and maintaining extension either of the leg or thigh. From the upper margins of the hollow for the knee proceed downwards two bars of iron, at a distance of six inches from each other, these are united at the bottom by a cross-bar at a distance of twenty-two inches from the knee. The space between these parallel bars is vacant, except for about three inches below the flexure on which the knee rests. A screw plays through the cross-bar at the bottom, by means of which is moved a foot-piece which slides along the parallel bars with a steady motion. To the foot-piece is affixed, by means of straps, which regulate accurately its height, &c., a shoe made of soft materials, and provided with straps and buckles for fixing it firmly to the ankle and instep.

"It will appear obvious that in fractures of the leg, whether simple or compound, when the knee is made a fixed point, and the foot properly fixed in the shoe, extension to any degree can be made with ease by means of the screw which acts upon the foot-piece. When turned in the proper degree, the screw is prevented from further motion by means of nuts which are brought close to the cross-bar through which it plays,"—pp. 3—6.

Mr. Greenhow narrates a case of compound fracture of the tibia, which was put up in the apparatus, and in which the constitutional disturbance was much less than usually occurs in such cases, and which terminated favourably. In fractures of the femur, more especially near the upper part, the difficulty of maintaining extension and perfect apposition of the fractured ends of the bone by the means in general use are very great; in such cases Mr. Greenhow recommends the instrument to be thus arranged.

"The limb must be placed upon the apparatus, supported upon the sling, the height of which must be regulated according to the length of the femur, by turning the perpendicular screw. The knee must be rendered a fixed point as before, by buckling the straps above and below its flexure. The back portion of the apparatus must be made (by means of the moveable slide) to reach to the tuberosity of the ischium; and the outer portion, which passes on the outside of the thigh, parallel with the bone, and has an iron leaf at the upper end, for the reception of a groin and a pelvis strap, must be extended by the screw to the degree required. Of course, the groin strap must be properly adjusted before the extension is made. The power of this screw will be found very great, but it can be used with so much caution, and so gradually, as to ex-

verdigris in the same form, and all and everything of a caustic, destructive, or irritating nature. Cataplasms and fomentations are the only local applications of which, in the course of his experience, he is able to speak favourably and with the least reserve. None of the measures he has witnessed the influence of, appear to have produced a cure in a shorter space of time than many months.—TRANSLATOR.

clude all hazard of mischief. When the proper degree of extension has been accomplished, the pelvis strap ought to be applied, by means of which, in fractures of the neck of the femur, or in the neighbourhood of the trochanters, the broken surfaces can be pressed together with any degree of force that may be required. The position of the iron loop, to which the pelvis and groin straps are fixed, standing off as it does from the general course of the outer line of the apparatus, and projecting above the great trochanter, renders it a most advantageous point for effecting both counter-extension and co-aptation by compression. A splint may now be applied to the anterior surface of the thigh, and the whole bound down by the straps which pass through the apertures in the back part of the apparatus."—pp. 10, 11.

We have thus given an outline of Mr. Greenhow's apparatus; time and experience alone can justify its extended application to hospital and private practice. Messrs. Weiss and Son are, we believe, the manufacturers of it.

ON THE PATHOLOGY OF UTERINE DISEASES.

BY VERAX.

HAVING read in one of the late Numbers of your valuable Journal some observations on the pathology of uterine diseases, I am induced to offer a few remarks on them, and lay before your correspondent some facts which, in my mind, materially annul the view Philo takes of this class of diseases. The opinions now broached do not appear to be supported by even one link of practical evidence. It is first stated, that, in very many cases, the suppressed catamenia depend on disorders of the uterus and its appendages; now, I must beg to differ widely from your correspondent in this opinion: numerous are the instances where this secretion is stopped, but it is distinctly traced to a sluggish state of the liver, or torpid action of the bowels, the face becoming tinged of a citrine colour, and, lastly, the uterus becomes implicated in the general disturbance of the chylipoietic viscera, as an effect of the former. The organ does not suffer from this derangement until the period arrives

for its peculiar secretion, and then the flow is scanty, pale, and followed by leucorrhœa, which I take to be merely a secretion of the vaginal vessels, induced by the debility of the uterine system.

When your correspondent alludes to the absence of the hysterical symptoms in uterine disease, I am surprised he does not clearly draw that most important diagnostic distinction between functional derangement and organic disease. The former affection is sometimes productive of hysteria, but in disease the vessels are employed in a morbid process, and are depositing, or taking away, some solid matter from the structure of the organ; is it, then, surprising, that the catamenia should not be secreted, and that the hysterical symptoms, referred by Philo to absorption, should be absent? he must be contented with the plain fact, that every morbid process will destroy a healthy one.

The fact of patients labouring under phthisis not being the subjects of hysteria is certainly novel and, I think, unfounded; if Philo will employ a leisure hour in perusing the Aphorisms of Hippocrates he will find that the father of physic noticed the great excitement of the uterine system in this disease, and his relation of the symptoms strongly indicate his knowledge of the disease.

Every practical man must have witnessed the common occurrence of globus hystericus, pain in the left side, headach, and palpitation in consumptive patients, where no catamenia are secreted.

Again; I would ask Philo what class of females can be named, who are so constantly under the influence of hysteria as pregnant women, and those who have passed the climacteric period, and yet here is no secretion. There are several cases on record of imperforated vagina, and one of these I would strongly recommend to the notice of Philo; it is detailed in the 86th Number of the London Medical and Surgical Journal for 1833. The uterus put on all the characters of

being six months gravid, when, on examination, it was found that the vagina was quite impervious, and the catamenia absent several months. The stricture was divided, the uterus emptied of its contents, which proved to be a collection of dark grumous blood, the accumulation of several months' secretion; the catamenia were ultimately established. Here was a total absence of hysterical symptoms; but Philo may answer, because the fluid was not absorbed, then if not absorbed, when its presence in the uterus, as an excrementitious secretion, must have been highly dangerous, how much the less ought we to expect that nature would summarily get rid of that fluid by absorption, which should be periodically thrown off to constitute health, and induce thereby a series of distressing maladies.

The fault I believe resides not in absorption, but in a depraved and debilitated system. Take as an example the case of a robust healthy girl from the country, who comes to London. She first becomes affected by the altered state of the atmosphere, from the diminished exercise of the body, and from changes of diet and scene; all these causes primarily act on the system at large, creating languor of the frame, loss of appetite, inability to use active exertion, and then the catamenial period arrives, and then also the effects of these changes of habit, &c., are seen, the flow is scanty, pale, or there may be a total absence of the secretion; then follow the long train of hysterical symptoms, the palpitating heart, chlorotic eye, œdematous legs, languid circulation, and debilitating leucorrhœa, all of which I conceive to be an effect of one great cause, the debility of the system at large; and the successful exhibition of steel and tonics as speedily remove them, as mercury will destroy the sequelæ of the syphilitic virus.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, November 9, 1833.

PROFESSOR BURNETT in the Chair.

*Character of Eruptive Diseases—
Influence of Climate on Health and
Disease—On Consumption.*

MR. CHINNOCK, Mr. Leese, Dr. Gregory, and others, remarked that vaccination was considerably modified this year, that moisture appeared to influence it, that it ought not to be communicated in wet weather. It was also remarkable that measles and small-pox had taken on a malignant type this year.

Mr. Preston thought that climate and season had great influence over health and disease. He alluded to the climate of the Azores, in which consumption was exceedingly rare.

Dr. Webster remarked, that he had visited many parts of Europe, and felt convinced that consumption was more prevalent in Italy than in this country. He also observed, that phthisis was much more prevalent among the Irish who attend the dispensary to which he is attached, than among the natives of England or any other country.

Dr. James Johnson corroborated the views of Dr. Webster. The mortality in Italy was 1 in 28, in this country 1 in 56. He had seen seventy-six consumptive patients in one of the Italian hospitals, a number he had never seen in any institution in this country. This climate upon the whole was the most salubrious in the world. It was colder than Ireland, and consumption was more common. The climate of Ireland was more damp and warm; consumption was not a frequent disease there; and the reason it attacked the Irish in London was on account of their poverty, intemperance, excessive labour, as they suffered more privations than the natives of any other country.

Mr. Preston mentioned a case of empyema, which elicited some remarks

from Dr. Johnson, Dr. Addison, and others. Dr. J. advocated the performance of the operation of paracentesis at a late period, Dr. Addison the early one.

MEDICAL SOCIETY OF LONDON.

Monday, November 11, 1833.

WILLIAM KINGDON, Esq., President,
in the Chair.

DR. UWINS was of opinion that the profession in general was too fond of generalising from a single cause, while difference of constitution or temperament was overlooked. He felt convinced that the habit of body predisposed to, or was susceptible of, various diseases from the same cause. In illustration of this opinion, he would relate two cases that had lately fallen under his observation. One was that of a hotel-keeper, who was bitten in the back of the hand by an individual in a state of inebriety. This wound was followed by inflammation of the absorbents, suppuration in the axillæ, &c., and when this last had disappeared, by erythema of the face and neck. It appeared to him, that the state of excitement in which the person was, who inflicted the wound, was the cause of the symptoms of his patient, and that an individual still more excited would by wounding his opponent have caused worse effects. It was well known that hydrophobia was excited by the bites of animals which were not rabid, and that the disease might occur spontaneously. He went on to offer various illustrations of his opinion, and was disposed to believe that scarlatina, measles, and small-pox, were originally one and the same disease, and that we are in the habit of calling fevers by different names, though produced by the same cause.

Dr. Whiting could not assent to Dr. Uwins's explanation of the symptoms produced by the bite in the arm, as a wound inflicted by a nail or any other instrument would have produced the same results. He agreed with Dr. Uwins in ascribing a vast

deal to the state of the constitution. He was of opinion that all contagious diseases were produced at first by different causes from contagion, and this led him to hear Dr. Tytler's facts about bad rice, which might, according to his views, have caused cholera in the first instance.

Mr. Proctor observed, that simple fevers might be converted into contagious or typhus by bad management, and that it was extremely difficult to decide what fevers were contagious.

Mr. Headland fully agreed with Dr. Uwins, in thinking that the profession generally fell into error in their views of the causes of disease; and that the nomenclature would be greatly improved by the inductive method.

Dr. Uwins remarked, that it was impossible, in the present state of our knowledge, to discover the causes of contagious diseases. All our eudiometrical and meteorological experiments had completely failed.

The remainder of the discussion turned on hydrophobia, in which no new fact was stated.

MEDICO-BOTANICAL SOCIETY.

Tuesday, Nov. 12th, 1833.

DR. CHOWNE in the Chair.

VARIOUS presents from foreign correspondents were acknowledged.

Dr. Sigmond, as secretary to the society, observed that it became his duty, in consequence of the absence of the noble president, Earl Stanhope, to give an account of the progress and prospects of the society, on the commencement of another session. He had also to notice the advances of all scientific investigations connected with the objects of this institution. He had first to inform the society that their medal to M. Rosseau of Paris, for his discovery and employment of ilicine, had led to the best results. The French government ordered their military surgeons to procure it as a cheap substitute for quinine. It was

prepared from the *ilex aquafolium*, or common holly. The next important subject he had to notice, was Dr. Tytler's inquiries on the bad effects of deleterious rice. It appeared to him that that gentleman had fully established the important conclusion, that deteriorated rice and other grain produced very fatal diseases; but as he was present, he would perhaps favour the society with some observations on the subject. Dr. Sigmond then alluded to Mr. Laming's mode of preparing hydrocyanic acid, M. Bonasto's analysis of manna collected from the *Larix Europæa*, M. Dubalon oil of aniseeds, Mr. Walsh on arrow-root, and lastly on a packet presented to the society by M. Pelletier, containing twenty specimens of the alkalis. The learned secretary then read an extract from the American Journal of Science, on the sedative properties of the white-ash on the rattle-snake, which appeared in a late number of this journal. He then passed a high eulogium on the noble President, the Professors, and Fellows of the society, and felt convinced that the present session would be the most interesting since the establishment of the institution. He need scarcely remind the Fellows that the Secretary of State for the colonies, the heads of the army and naval departments, were patrons of the society, and afforded facilities of receiving information from all parts of the globe. Wherever the British flag appeared, there was a man of science to collect information; and as in our present state of knowledge the immense field of medical botany was far from being explored, we have the best opportunities of acquiring knowledge on the noble objects we have in view.

Dr Tytler assured the Society that he had seen a native of India hold a dried plant in his hand, and a scorpion on his arm, and that the animal though irritated would not bite, but turned its sting backwards. He had also seen an Indian present a root to the *Capro da Capello*, and the animal retired immediately. The fact about

the sedative power of the ash was, in his opinion, true, however incredible it might appear to some individuals.

Dr. Ryan wished to inquire whether Dr. Tytler had observed many such experiments as he had mentioned.

Dr. Tytler replied, that he had witnessed several; and that General O'Halloran had written a paper on the subject, addressed to the Medical and Physical Society of Calcutta.

Dr. Tytler then addressed the Society on the rice question. He said he had been thirty-one years engaged in his profession, and that the facts he had collected, though contrary to preconceived opinions, must be sooner or later admitted. They prove, beyond all doubt, that the cholera at Jessore, in 1817, was caused by bad rice. He might quote a host of authorities, sacred and profane, in attestation of the fact, that deterioration of grain preceded various pestilences. He cited many passages from the sacred, classic, and medical writings in support of this opinion, which were extremely apposite. He never argued that rice was the *only* cause of cholera, but might certainly induce the disease. He referred to his own observations at Jessore, which proved the fact beyond all doubt. He would explain, very briefly, to the Society the manner in which bad rice was introduced, and continues to be introduced, into Europe. In 1813 the Free Trade Act was passed, which allowed competition with the East India Company. Before that year the Company was the government of India, and the natives dare not sell bad rice. But minor commercial men were then let into the markets, and as their capitals were small compared to that of the Company, they bought the cheapest and worst article. The natives were under no fear of them, and supplied the refuse of rice, which they dare not offer to the Company. There are two crops of rice, one cut in the wet months, which is bad, the other in the dry season. The former is sold by the natives to the free-traders of

these and other countries, and is introduced into all parts of the world. When ground and mixed with wheaten flour, meal, arrow-root, tapioca, and other farinaceous aliments, it is almost impossible to detect it. In 1825 it destroyed the troops in India. Suppose our fleet was sent up the Baltic, and fed on rice, what would be the consequence? Dysentery or cholera; and when ordered home we should have the authorities declaring these diseases contagious, that quarantine was necessary with all its evils. Now, he would show that the last stage of Indian cholera, plague, and the English sweating sickness were similar in all respects. A Mr. Lane had called on him, and on hearing his views on the bad effects of deteriorated rice, declared that he considered the plague of Egypt produced by bad rice and other grain. If, then, deteriorated grain can cause cholera, dysentery, gangrene, and plague, what need have we to consider contagion the only cause? He felt convinced that this was a fatal error, and one of the most injurious and destructive to humanity.

A vote of thanks was unanimously passed to Dr. Tytler for his laborious inquiries, and for the important information he had communicated to the Society.

The meeting then adjourned to Tuesday the 26th instant, when Professor Burnett will lecture on the fungi.

**THE LATE MEDICAL OFFICERS OF
THE ALDERSGATE-STREET DISPENSARY.**

WE have received the resolutions of the Profession in Birmingham and Liverpool, highly complimentary to the late medical officers of the Aldersgate-street Dispensary. We regret that our space does not enable us to insert these communications.

THE Superintendence of the Fermoy Dispensary and Fever Hospital is vacant by the death of Dr. M'Namara.

**THE
London Medical & Surgical Journal**
Saturday, November 16, 1833.

**THE LATE MEDICAL OFFICERS OF
THE ALDERSGATE-STREET DISPENSARY AND THEIR SUCCESSORS.
—MEDICAL ETHICS.**

OUR contemporary, the *Lancet*, has, in his last Number, suggested to his readers, that all professional men are bound to refuse to consult with the present Medical Officers of the Aldersgate-street Dispensary; and he compares their conduct with that of Dr. Ramadge, in commending "the rubbing practice of the cruel destroyer of Miss Cashin." The cases are by no means similar. Dr. Ramadge, in open violation of the moral statutes of the Royal College of Physicians, not only lauded a notorious illiterate quack, but maintained that he was as competent to treat disease as all the members of the Colleges of Physicians and Surgeons*. This was the grossest violation of medical etiquette and ethics ever perpetrated by a FELLOW or Member of either College; and though that body which has the honour of having his name adorning their roll of great men, took no notice of their worthy colleague, the profession looked on the matter in a different manner, and resolved to refuse meeting the advocate of quackery in consultation. But the present Medical Officers of the Aldersgate-street Dispensary have violated no

* See Letter in the *Sunday Times*, May 31. 1831, and in Vol. I. of this Journal.

moral statute, no known professional rule, in taking office under the self-interested and money-making Committee, who insulted the medical profession. It is true, they acted in a mean pitiable manner—in such a way as really independent members of the profession would not have acted. But there is no disputing about tastes; and we leave them to their own bitter reflections. They have now to consider that the profession throughout the kingdom has approved the manly conduct of their predecessors, fraught with the most beneficial results. But our contemporary inquires, “are they, then, to be joined in consultation by the respectable members of the profession?” We say most certainly, as they have not acted contrary to a single moral statute of the profession. Neither have the speakers at the late meetings, concerning the ex-medical officers, acted with pusillanimity or disgust, in avoiding personalities, while advocating an excellent principle.

No one can accuse us of apathy or indifference to the respectability and dignity of our profession; we have suffered more in its defence than the majority of our brethren; but justice compels us to state the question fairly. We proposed the strongest resolution against the conduct of the present medical officers, but we see no ground for refusing to meet them in consultation, or for expelling them from any medical society to which they may belong. We agree with the sentiments of all the resolutions adopted

at every meeting of the profession, returning cordial thanks to the late able and independent Medical Officers; and we deeply regret that individuals could be found to accept the offices they vacated in endeavouring to crush the hydra of corruption, which has so long injured the progress and fame of medical science, and the interest of our afflicted fellow creatures. But as the medical officers of nine-tenths of the hospitals, infirmaries, and dispensaries in this section of the empire have accepted offices under this iniquitous system, it would be as just to refuse to meet these in consultation as the officers alluded to by our contemporary. The time, however, is at hand, when the principle defended by Drs. Birkbeck, Clutterbuck, Lambe, and Roberts, and Messrs. Salmon and Coulson, and subsequently by the profession at large, will be enforced by the legislature in protecting the public health.

DETERIORATED RICE AND GRAIN THE CAUSE OF CHOLERA, PLAGUE, &c.

WE direct the attention of our readers to the report of the proceedings of the *Medico-Botanical Society*, which will be found in another page, which satisfactorily prove the bad effects of injured rice on the human constitution. We think the public and the profession greatly indebted to Dr. Tytler, for the very important information he has collected and communicated, which deeply interests all civilised nations*.

* Facts establishing the deleterious properties of Rice, used as an article of food. By Robert Tytler, M.D. Renshaw and Rush.

It appears to us, that the statements of this experienced and judicious physician deserve the serious consideration of the government and the public press, not only of this but of all other countries. His facts go far to extinguish the direful doctrines of contagion, which lead to a violation of every duty of humanity.

The proceedings of the *Medical Society of London*, and the *Westminster Medical Society*, which will be found in this number, are also worthy of careful consideration.

OBSERVATIONS ON VACCINATION AND SMALL POX.

BY THOMAS HAREWOOD, ESQ., SURG., DERBY.

MORE than thirty years have now elapsed since the late Dr. Jenner established the practice of vaccination throughout this country, and upwards of five-and-twenty since a diminution in the mortality from small pox began to be felt. Since the latter period, however, a most sensible and striking effect has been produced by the protecting power of this inestimable discovery, in this country, as well as in most of the civilised nations of the earth. But, as several instances of small pox have lately proved fatal in this town and neighbourhood, the attention of the medical public has been called to some investigation of the subject.

In the course of the inquiry touching the repeated appearance of this disease, the principal evidence which presented itself applied to two or three descriptions of persons. Those in whom the disease manifested itself in its most fatal and appalling form consisted of children of the lowest class, who had never been subjected to the power of vaccination. The next description consisted of those who form the most numerous class in all great

communities, such as the better order of mechanics and inferior tradesmen, amongst whom the modified, or what is usually termed the *five days' small pox*, generally prevailed. Under this head may be comprised the greatest number of those who had undergone the test of previous vaccination, and amongst whom no instance of fatality has yet been recorded. The powerful illustration which vaccination here afforded in its own favour was unequivocal even to the most sceptical and indifferent, evidently showing that the mortality in small pox prevailed amongst that portion of the population who neglected to put their children under the more benign influence of cow-pox;—a blessing which it is much regretted the lower orders, as well as the guardians of the poor, do not more deservedly appreciate.

During the prevalence of this disease, a circumstance presented itself in those cases of small-pox subsequent to vaccination, which has hitherto escaped notice. The nearer to mature age, or those who had received vaccination at the most remote period of time, the more aggravated was the disorder, and the more protracted the recovery; while children of more tender age, who had but recently been the subjects of the vaccine disease, passed through the attack with, comparatively, no inconvenience. This leads me to the consideration of the question,—Whether it would not be highly desirable to adopt the practice of re-vaccination after the lapse of a given time—say seven years, or some such period. By this means, a satisfactory test would be afforded as to the extent of the vaccine influence on the constitution, or an opportunity of re-establishing the protecting principle, which the course of time may have obliterated.

Although vaccination does not possess the power totally to exterminate the small-pox, yet it provides an influence adequate to the great end contemplated by its learned discoverer—that of a protection to the constitution against its virulence and fatality.

It is, therefore, a consideration of the deepest importance to society, that the broad distinction that exists between true small-pox and that which follows vaccination should be viewed in its true light, in order as much as possible to remove the unmerited discredit in which vaccination is sometimes held by the prejudiced and the uninformed.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Excision of a Tumour from the Thigh —Excision of a portion of the Superior Maxillary Bone—Castration.

On Saturday, October 26th, three operations were performed in this hospital by Mr. Earle. The first was the removal of an encysted tumour from the thigh of a young woman. The cyst was very deeply seated, lying immediately over the femoral artery. The next was the amputation of a projecting portion of the superior maxillary bone, in a child three years old, who had also double hare-lip. Mr. Earle postponed the operation for hare-lip until another day. The third operation was the removal of a portion of the testicle, in a young man aged 24. In this case there was a growth of the testicle through the scrotum, which not being of a malignant nature, Mr. Earle determined to remove only a portion of the organ. Having made two semilunar incisions with a small knife, one on each side of the diseased part, Mr. Earle sliced off about one-third of the body of the testicle. The hæmorrhage was trifling. After the operation Mr. Earle made the following remarks.

"Gentlemen,—In this case there was scrofulous growth of the testicle through the scrotum. Now in former times this disease was considered malignant, and castration was always performed in such cases. The disease, however, is not malignant, and accordingly in later times we have had recourse to the comparatively mild operation which you have just seen performed. On a section of the portion which I have removed, you will of course perceive the seminiferous tubes; inflammation takes place around these tubes, and adhesions ensue between the testicle and scrotum. I have seen very many cases in which the removal of part of the testicle was completely successful; the integuments being drawn together, the wound healed by the first intention. This patient wished to have the entire testicle removed, but I am anxious to try the success of this operation. Of course a sufficient quantity of the testicle has been removed to destroy all

sexual purposes. This disease is very likely to be confounded with growth from the tunica albuginea. In these cases, in which the body of the testicle is affected, you will find a flow of semen from the testicle, and if a clean linen cloth be placed around the testicle, it will be moistened with a viscid fluid, evidently semen. By means of this characteristic you can always distinguish disease of the body of the testicle from that of the tunica albuginea."

Fungoid Excrescence of the Tibia.

In the Journal of the 14th September last we reported a very interesting case of fungoid growth from the tibia, for which the novel operation of scooping out the morbid mass was performed by Mr. Lawrence. We then promised to give the results of the operation in a future number, and since the operation the case has gone on as follows:—

On the evening of the operation the patient appeared to suffer most exquisite agony, and he was ordered to take forty drops of tincture of opium, which succeeded in bringing on a sound and long continued sleep.

Sept. 17. Feels very comfortable this day; the wound presents a very healthy granulating aspect.

Haustus salin. 3 ss. *4tis horis.*

Olei ricini 3 ss. *cras mane.*

The patient went on remarkably well in every respect until the beginning of October. Bowels regular; slept well.

Oct. 3. A change for the worse took place. He seemed to suffer considerable pain; pulse very frequent; skin hot; bowels irregular; the surface of the wound presenting a very unhealthy appearance,—evidently erysipelatous. Apprehensions were entertained of the return of the original disease, which will probably ensue.

ST. GEORGES'S HOSPITAL.

Fracture of the Humerus and Radius —Amputation—Death.

William Gilchrist was admitted some weeks since, under the care of Mr. Keate, with compound fracture of the left humerus, and simple fracture of the right radius. The accident had been occasioned by his falling from a platform laden with stone, at the new buildings attached to King's College. The compound fracture was so severe, that Mr. Keate decided upon amputating the arm above the situation of the fracture, which was done four hours after his admission. The man bore the operation remarkably well, and the stump soon put on a healthy appearance; an abscess formed in the surrounding cellular texture, which was opened, and discharged freely; the man's health did not, however, appear to suffer materially until within thirty-six hours of his

death, when his spirits began to sink, and symptoms of serous effusion upon the brain were manifest, which gradually increased, and he sank.

On a post mortem examination being made, the vessels of the brain were found distended, and the lateral ventricles filled with serum, and a small abscess was discovered connected with the cerebellum, which appearances may be considered as having formed the proximate causes of death.

*** We perceive by a report in the Times newspaper, that an inquest was held upon this man, in the course of which some rather irrelevant remarks were indulged in by a brother of the deceased, tending to throw blame upon those under whose care he was placed whilst in the hospital. We had frequent occasion to see him whilst in the hospital, and have as often heard him express himself grateful to Mr. Keate and Mr. Hicks, (the house-surgeon) for their uniform kindness to him. We are also convinced from our own knowledge, that every attention possible was paid to him. We have not the means of accurately disputing the fact of his not being allowed a night-nurse to attend upon him; but this we can say, that during the whole of our pupillage at St. George's we never heard a more foolish, groundless, or vexatious complaint made, and we therefore believe it to be totally and completely false. On the necessity of a post mortem examination we need not remark; the case demanded it, and Mr. Hicks could not have given his evidence without it. The exclamation of the nurse, respecting headaches, was one of those unfortunate sallies of wit to which Irish maidens are sometimes prone; a word of advice to her on the subject will completely check its future recurrence.

Clinical Remarks by Mr. Brodie.— Corns.

Corns are generally compound bodies, composed of a disorganised thickened cuticle above and an inflamed bursa beneath. They are generally caused by pressure, and if you relieve that pressure, you either cure the corn, or at all events remove the exquisite pain in them; for they are very painful, and frequently lame the person who suffers under them when they inflame and suppurate. You will find hard corns on the surface of the phalangeal joints of the toes, and soft corns occur frequently on the fourth and the little toe, which latter is generally caused by the tight shoe pressing the end of the little toe under the other. You will sometimes find a thick fungous cuticle on the inside of the great toe nail; this is caused by the pressure of the next toe on one side, and the nail of the great toe on the other. The necessary treatment to relieve all these, is to take off the pressure causing them. Where there is this thick fungous cuticle which I have

mentioned, you may cut and pare away the nail as long as you like, but you will not relieve it until you have taken off the pressure, (a gentleman present here remarked, that the French surgeons in these cases removed the entire toe-nail). Wherever the corn is situated there you must remove the pressure, and the best way to do this, is to put a piece of thick buff leather around the corn, leaving an aperture in the middle for the corn; this, you will find, will relieve the pressure considerably. For soft corns between the toes the best thing you can do is to place a piece of this same buff leather between the toes, and by keeping them thus apart, you relieve the pressure at the bottom between each. These remarks were made with reference to a man in whom the end of the second toe was pressed downwards, and the second phalangeal joint was raised, with a hard corn on its summit, to relieve which Mr. Brodie strapped it down, even with the other toes, by passing strips of adhesive plaster *over* the corn and *under* the adjoining toes. Mr. Brodie remarked, that this plan frequently succeeded, although he feared that this patient was too old for it to prove of material benefit to him.

Calculus Vesicæ—Lithotomy—Death.

George Young, a boy of scrofulous appearance, æt. 9, was admitted Oct. 2nd, under the care of Mr. Babington. He stated that he had been afflicted with, and suffered from, symptoms of stone in the bladder, as far back as any period he could recollect, and that some short time since he voided blood with his urine. He complains of no pain when pressure is made upon the region of the abdomen, nor has he any pain in passing his water, or afterwards, which latter symptom he had some time since. Has no tenesmus, and can retain his water perfectly well at night. The calculus can be easily detected by the sound; urine acid. The general state of his health was attended to, and his bowels were kept open, and he had ordinary diet.

16th. *Olei ricini*, ʒss. *hæc nocte sumend.*

17th. The operation of lithotomy was performed by Mr. Babington. Nothing worthy of remark occurred during the progress of it. Some little difficulty was experienced in extracting the stone, which was of a large size. Fever diet.

R. Pulv. ipecac. comp. gr. iij.

Hæst. salinæ ʒj. Miscæ, fiat hæst.
4tis horis sumend.

Nine P.M. No bleeding has occurred from the wound, and the urine has flowed freely through it. Pulse 120. He appears very feverish and restless. Tongue white and dry.

18th. Continued very restless and uneasy during the whole of last night, and slept only at short interrupted intervals. Tongue brown, dry, and parched; complains of great thirst; pulse 120; abdomen swelled and tym-

panitic, and very tender. Complaints of pain when pressure is made over the region of the pubis, but not higher up. The urine was tasted but not found acid. Was sick twice during the night after taking his medicine.

R. Haust. ammoniæ citrat. salin. c. ammon. carbon. gr. iij. in excess. 6tis horis sumend.

Baln. tepid. vespere.

R. Olei ricini ʒij. statim sumend.

Six P.M. On visiting him we found his pulse at 140, small and weak. He had been in the bath about twenty minutes, when he complained of great faintness, and was removed to bed and slept very sound for a short time.

Eleven P.M. Worse in many respects; pulse sunken and weak; abdomen tympanitic; pain on pressure has extended higher up towards the umbilicus; the bowels have not been relieved since the operation.

Repet. haust. salin. in statu efferves. c. sacchar. alb. ʒss.

19th. On visiting him this morning we found that he had been very restless and uneasy during the whole night; had slept but little; refused to take his medicine, but took a small quantity of the castor oil, which operated once. The tympanitic swelling of the abdomen has diminished since yesterday; complaints of pain on pressure over the whole surface of the abdomen. He vomited twice after his breakfast this morning, and brought up from his stomach some thickened coagulated substance resembling curd, but which the clinical reporter of the case states to have the appearance of cheese soaked in water. He has been in the bath again to-day for about ten minutes, from which he felt much relieved. Pulse 135 and weak; skin hot and dry; tongue dry, brown in the centre and red at the edges.

R. Vini albi, ʒij. Soda water.

10 P.M. He appears better in every respect; skin cooler; pulse less quick, 124, and firm; not near so restless; tongue moist and clean; less tenderness over the abdomen on pressure; has had no evacuation from the bowels since that produced by the castor oil.

20th. Slept very little during last night, and was very restless. Had two evacuations from the bowels during the night and one this morning. Tenderness of the abdomen is quite gone, except just above the region of the pubis, where it still remains; has not had any return of sickness, and could not be prevailed upon to take his medicine. He was in the bath this morning for a short time, which relieved him very much. Pulse 120, small and weak; tongue moist and red, but he does not complain of much thirst; face flushed, but the general surface of the body is cool. He was ordered gin ʒij, beef-tea Oj.

21st. Much better to-day; less restlessness; complaints of pain in the stomach, which, however, is not increased by pressure. The gin and water caused a slight degree of sick-

ness this morning. There has been no evacuation from the bowels since yesterday. He complains of some pain in the wound, which on being examined was found to have a dark unhealthy appearance. Tongue red and dry, without much thirst; pulse 120, weak and full. A linseed-meal cataplasm was ordered to be applied to the wound.

22nd. Very restless during the past night; no appetite; has taken no solid food since the operation; was placed in the bath this morning from which he expressed himself much relieved; has had no evacuation from the bowels since yesterday; tenderness of the abdomen the same as at last report; wound has put on a sloughy appearance; poultice could not be kept in close contact with the wound, which was ordered to be washed instead with the solution of chloride of lime; was sick this morning and brought up some dark-coloured fluid from the stomach; pulse 125, very small and feeble; tongue red and dry in the centre, but not furred.

23rd. Died at half-past 12, P.M.

Autopsy.—On laying open the cavity of the abdomen there were found depositions of pus in various parts of it. The urinary bladder was healthy in appearance except at the spot where the incision into it had been made, which was in a sloughy state, as was the cellular membrane immediately surrounding it. The whole exterior surface of the bladder was embedded (if we may so speak) in pus. The kidneys were found diseased; they were larger in size, paler in colour, and softer in texture than natural; the cortical portion of each was apparently contracted, and the infundibula were dilated. There was an effusion of pus and serum between the peritoneum and dorsal muscles, and the cellular membrane was in a sloughy state as high up as the diaphragm. The viscera of the thorax were healthy.

WESTMINSTER HOSPITAL.

Extraordinary complication of Symptoms—Cholera—Premature Labour—Death.

J. H. a young woman, about nineteen or twenty years of age, was admitted into the hospital about the middle of August last, complaining of very severe pains in the right hip, resulting from a fall which she stated she had received a few days previous. About thirty leeches were applied to her groin, which afforded great relief, as the uneasy sensations in the hip disappeared, but were soon succeeded by various symptoms indicating the presence of cholera. The eyeballs became retracted, and the countenance drawn up; pulse very small; body cold. She was ordered to take effervescent draughts every hour in the day. The symptoms of cholera gradually became less marked, and eventually disappeared. Her countenance put on its natural appearance,

and her stools were more healthy. Pulse about 93, soft; bowels open.

Towards the latter end of the month the patient suddenly became worse, and complained of very violent pains in the hypogastric region and abdomen. A few days after these, bad symptoms had set in, the patient was delivered of a fœtus about 12 weeks old. This occurrence took place without the knowledge even of the nurse, and it appeared that she had attempted herself to detach the placenta, but her exertions to accomplish this object were ineffectual. She concealed her delivery from all the attendants until the morning visit of the house surgeon of the hospital, who discovered her situation. Her pulse at this time was exceedingly rapid, and she appeared to labour under great nervous irritability. The house surgeon endeavoured to remove the placenta, but found it attached to the fundus of the uterus. Soon after she complained of the recurrence of violent pains in her hip, and died shortly after.

On a post-mortem examination the general aspect of the abdominal viscera was healthy, and a large portion of pus was found in the peritoneal sac. The uterus was somewhat contracted, and there was ulceration of the cartilage of the cotyloid cavity of the right side.

Mr. White was interrogated by one of the pupils respecting his opinions with regard to cholera. Mr. W. said that he did not agree with Mr. Brodie in his opinion that cholera was always preceded by diarrhœa; his practice did not strengthen the assertion.

On Saturday, Nov. 9th, after his clinical lecture, Mr. Guthrie proceeded to tap a very large hydrocele. Mr. G. at first intended to inject back the fluid which came from the hydrocele, but postponed the injection, remarking, that in cases of such large hydrocele as the one present, it was advisable not to inject immediately, but to allow some days to elapse before the injection of the fluid.

Erysipelas of the Arm—Cure by Incisions.

Short incisions, about three or four inches in length, were made in the arm. This treatment was originally recommended by Mr. Guthrie, in his work on Gun-shot Wounds. The principle on which incisions are made, is to diminish the tension of the parts, and thus lessen the erysipelatous tendency. In this case, incisions have been crowned with complete success.

MEDICAL ASSOCIATION OF THE COUNTY OF LINCOLN.

WE have much pleasure in informing our readers that a Medical Association has been formed in the county of Lincoln, for the purpose "of encouraging fair and liberal conduct among

medical practitioners, promoting their social intercourse, and supporting the rights and privileges of the profession." Every other shire should have its Association. The above Association proposed and carried unanimously a vote of thanks to the late Medical Officers of the Aldersgate-street Dispensary.

ROYAL COLLEGE OF SURGEONS.— CERTIFICATES UNDER FALSE PRETENCES.

THE following circular has been addressed to all the lecturers in London.

*Royal College of Surgeons in London,
31st October, 1833.*

SIR,—I am directed by the Court of Examiners to acquaint you that certificates of attendance on lectures have been offered to the Court, in order to entitle the candidates to examination for the diploma of this College, which certificates the Court are fully satisfied were obtained under false pretences.

I am further directed to request you will inform the students composing your class of the extreme dissatisfaction and regret with which the Court have made this discovery, and that you will assure them the Court will in future punish, with the utmost severity the law admits, all persons who may be implicated in a similar offence.

I am, Sir,
Your most obedient, humble servant,
E. BELFOUR, *Secretary.*

MISCELLANIES.

EDINBURGH TOWN COUNCIL, Nov. 2.—An extraordinary meeting of the Council was held to-day at one o'clock. The Lord Provost said it was his most agreeable duty to lay upon the table an act passed by his Majesty in favour of the Town Council, vesting in that corporation the future appointment of the Professors of Medicine and General Pathology, and Medicine and Surgery, in consequence of the liberal,

impartial, and judicious use they had hitherto made of their academical patronage, and reposing great trust and confidence in their future discretion in this respect. The warrant was then read and received with applause. His Lordship stated that this warrant was executed 15th July, but was refused to be subscribed by his Majesty until he had made the proper inquiries into the conduct of the Council, which he had most graciously done personally, and having met with his high approbation, he had surrendered his patronage in their favour.

ELECTION OF SURGEON TO THE HUDDERSFIELD AND UPPER AGBRIGG INFIRMARY.

ON Wednesday, the 30th of October, the election of Surgeon to the above Institution, vacant by the death of Mr. John Atkinson, took place in the Court House at Huddersfield. The candidates for the office were Mr. J. T. Bradshaw, Mr. T. R. Tatham, Mr. James Astin, Mr. T. Wrigley, and Mr. William Greenwood; but the two last mentioned gentlemen withdrew before the election took place. The attendance of subscribers was numerous and respectable, there being before eleven o'clock, the hour appointed for the commencement of business, not fewer than four or five hundred gentlemen present. The poll commenced at twenty minutes past one o'clock, and terminated at a quarter past three, as follows:—

Mr. Bradshaw	291
Mr. Tatham	225
Mr. Astin	64

Majority in favour of Mr. Bradshaw 66.

WE are happy to find that the Brecknock Infirmary is likely to be soon opened. At a meeting of the subscribers, held last week, at which Col. Wood, M.P. for the county, presided, it was resolved that the building should be completed forthwith. Arrangements were at the same time made to open the Infirmary for the reception of patients about the beginning of November.

LIMERICK.—The gentlemen of the Profession in this city purpose, we understand, to establish a medical library in Barrington's Hospital, which will be a valuable acquisition to the Faculty and the public.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, November 7th.

Thomas Common	Newcastle-upon Tyne.
Joseph Douglas	London.
Fred. Atcherley Edwards	Ellesmere, Salop.
George Northon Foaker	Colchester.
William Greenwood	Arneside.
John Lumley Sudbury	Newark, Notts.

CORRESPONDENTS.

A. B.—The case was grossly mismanaged, and had an inquest been held before a medical coroner, the surgeon would have been committed to the Old Bailey.

X.—The proposed plan will lead to imprisonment, if detected by the Company of Apothecaries.

A duped Apprentice.—The Hall cannot recognise the indentures of an illegal practitioner.

The Plumstead Inquest.—We cannot offer an opinion upon the authority of newspaper reports.

A Dublin Correspondent.—We shall be happy to receive communications on the projected reform in the Irish Hall.

Mr. Palmer.—We shall feel pleasure in inserting the articles mentioned.

Mr. Stritch.—We are much obliged by the communication, and thank our friend for setting his illustrious preceptor right with regard to us. We shall have great pleasure in doing him ample justice when we have an opportunity.

A Middlesex Correspondent.—We request our friend will continue his communications. We should be happy to see him.

A Borough Student.—It is impossible—no Lecturer could be so vain and foolish “as to advise his class to read no book, but depend upon his own lectures.” An American author soberly declared a short time since, that it would be an advantage if all medical works were burned.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

No. 95.

SATURDAY, NOVEMBER 23, 1833.

Vol. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXIV., DELIVERED MARCH 7, 1833.

GENTLEMEN,—I mentioned yesterday evening, that in rickets, the bones become unnaturally brittle, and in the subject from which this skeleton was taken, the bones of the leg were fractured, from some slight cause or another, in the dissecting room. Now, you will find it generally observed in works on surgery, that rickety bones which happen to break, will not unite again favourably; either that the union is brought about very tediously and slowly, or is not completed at all, while, in some instances, it is only of a fibro-cartilaginous nature. But, as far as my own experience goes, I should say, that bones affected with this disease generally unite much better than might, *a priori*, be expected. No doubt, when the disease exists in an extreme degree, there may be considerable difficulty in effecting the union of their fractures, and sometimes there may be no disposition to form callus at all. I observed also in the last lecture, that the common period of the commencement of rickets is between the ages of eight months and three years; but you ought to be apprised, that the disease may begin in the fœtus before birth, of which fact I now show you an example. Here is the skeleton of a fœtus, which exhibits a strongly marked rickety condition of the bones. It was likewise explained to you at our last meeting, that the heads of rickety individuals are generally very large, the bones of the cranium exceedingly thick in some places, and thin in others, and that the bones of the lower half of the skeleton are much less developed than those of the upper half. It is questionable, whether the bones, after the adult age, ever become affected with rickets for the first time. You meet with cases, in

which the deformity shows itself after puberty, the spine becomes twisted, or the pelvis disfigured; but I believe, in every example of this kind, the vertebræ and bones of the pelvis have never been rightly and fully developed; their formation has always been imperfect.

There is a deformity of the spine arising in young persons who are growing with great rapidity, especially in females, which does not depend on any disorder of the bones analogous to rickets, but on the circumstance of such individuals not exercising their muscles equally, or on their being prevented from taking the free and unconstrained positions and exercises most agreeable to nature. Under such disadvantages, the spine becomes deformed, without any imperfection in the texture or development of the bones, and consequently there is no rickety disease of them.

When curvature of the spine, which has arisen from such causes, is not too considerable, and the growth of the individual not yet completed, the deformity may be removed by letting all the muscles of the trunk be daily exercised in a free, regular, and uniform manner, so as not to suffer one set to be put more into action than another. It is on these principles that gymnastic feats and manœuvres become exceeding y useful in the treatment of deformities of the spine, which are so common in girls during their growth. However, if the deformity has been of long standing, it will be impossible to remove it in this or any other way; for the disease then approaches in its nature to that kind of deformity of the skeleton, which results from old age. Here, gentlemen, you see a specimen of a curvature of the spine, brought on altogether by the effect of old age; of course, the deformity, arising from the cause now specified, is completely irremediable. When the curvature is of the dorsal vertebræ, the upper part of the spine is usually inclined to the right side, as you see in the skeleton which I now show you, and the consequence of this is, that there is such an alteration in the position of the ribs, that there is a great convexity of them in the right side, and a flattening of them on the left; in this example, you see that the ribs are thrown in the direction I have described. Then the scapula is made

to project backwards, and the right shoulder is thrown forward. In consequence of the flattening of the left side of the thorax, there is hardly room enough in it for the proper action of the heart and the due expansion of the lungs. In many instances the spinal column is not merely curved, but twisted in a spiral manner, and perhaps this illustration of the fact, now adverted to, is one of the best preparations of the kind in London; you may notice, that there is not only a curvature of the spine, but a complete twist of it, insomuch, that in one part the spinous processes of the vertebræ are brought nearly round to where their bodies ought to be situated.

In some of these cases, the clavicle may be displaced, in consequence of the alteration in the position of the shoulder; that is, the sternal end of that bone may be thrown inwards so as to press upon the œsophagus. An instance of such displacement of the sternal end of the clavicle is mentioned in Sir Astley Cooper's work on Dislocations, and the pressure on the œsophagus was such, that the surgeon, under whose care the patient was placed, was obliged to remove a portion of the clavicle in order to prevent the fatal consequences which would have arisen from the impediment to deglutition. Gentlemen, the next preparations show you the alterations in the form of the female pelvis occasioned by rickets. Here, the pelvis has assumed a triangular shape,—the sacrum is displaced, and the ossa innominata are thrown inwards so as to give the pelvis a triangular shape. In rickety females, the bones of the pelvis, you know, are smaller than natural,—not properly developed, and, you see, that the pelvis, which we are now examining, is surprisingly small. In the museum, you may see the pelvis of an elderly female, the bones of which are very incompletely developed.

When there is a bend of the spine in one direction, there will frequently be another in exactly the opposite direction to counterbalance it, and sometimes there will be even a third curvature, so that the spine will represent an italic S, as illustrated in the excellent specimen, which I now place before you for examination. In rickets, the bones of the limbs may be bent laterally, and the convexity of the curve may be on the external side of the limb; here is a specimen, in which the bones of the leg are thus deformed. I have recommended the conservator to make a perpendicular section of this tibia with a fine saw, as I think it would show in an admirable manner the great thickness of the lesser curvature, compared to that of the greater; it is also a capital example of the flattened shape often communicated by rickets to a long bone, which ought rightly to be more or less cylindrical. These changes, as I have explained to you, seemed designed to confer strength in the particular part of the bone in which it is wanted.

With respect to the *treatment* of rickets, I may observe, gentlemen, that as the disease

consists in a congenital defect in the organisation of the bones, its removal, perhaps, scarcely admits of being effected but by nature herself. We know of nothing that has the power of so altering the texture of the osseous system, as to communicate to it a due consistence, to rectify the derangement of its nutrition, and promote its full development. While the bones are under the influence of these imperfections in their texture and nutrition, they gradually yield under the pressure of the parts above them, and to the action of the muscles connected with them; and hence they bend, and deformity ensues. Now, the question is, how can we counteract these two causes of deformity? One would say, of course, by keeping the muscles from acting, and taking off the weight of the parts most liable to affect the bones by their pressure on them. But, gentlemen, considerable difficulty is experienced in putting these principles into execution; for, if the individual be confined long in the recumbent position without being allowed to use his muscles, his constitution soon begins to suffer—he loses his strength—and his health gets into a state, in which no improvement in the texture and development of the bones can take place. Again, if you attempt to take off the weight of particular parts by mechanical means, by the use of machinery, the pressure will only be transferred to other parts; thus, in the application of machinery to take off the weight of the head, chest, and upper limbs, from the spine, you would be obliged to use the pelvis as a fulcrum, and thus deformity of the bones of the pelvis might be produced. You have seen the skeleton, which we possess, in which the humeri have been vastly deformed by the pressure of the crutches on which the individual supported himself. However, it is not my wish to declare, that the use of machinery in rickets should be entirely relinquished; perhaps, in some respects it is preferable to a rigorous observance of the recumbent position, in which the patient always loses his health. Experience teaches us, that whatever tends to strengthen the constitution has a decided tendency to promote the removal of the rickety disorganisation of bones; and as the individual grows and acquires strength, those parts of the osseous system, which the disease has deformed, will assume greater strength, and a better shape. In the treatment of rickets, therefore, it is always an important object to rectify any manifest disorder in the health, and in particular to keep up the child's strength. You will find many rickety patients more or less debilitated, emaciated, or big-bellied, and some of them plainly scrofulous. To these sea-bathing will prove eminently serviceable, care being taken to promote the cutaneous circulation by the use of the flesh brush, or friction with napkins. Tonics, and particularly steel medicines, will also be beneficial. When the curvature of the lower extremity is considerable, machinery may be applied, and when the deformity is conjoined with an inversion of the

foot, a great deal may be accomplished by means of mechanical contrivances sold in the shops. But I think that, where machinery is employed, the patient should be allowed to exercise his muscles for a certain period of the day. I have already told you, that many deformities arising from rickets may be cured entirely on gymnastic principles, that is, the patient is obliged to follow up a certain train of exercises, which put all his muscles into regular and equal action; and one principle is to put into action the antagonists of those muscles, whose preponderating activity and strength have led to the deformity, as well as those muscles themselves. Thus, when the spine is drawn to one side, by the right arm and shoulder being used more than the left, the object is to put the muscles of the left side into regular exercise, in order to counteract the effect of the muscles of the opposite side. Mr. Til-leard Ward's great success in the treatment of deformities depends, I believe, upon the skill with which he puts these principles into practice.

Gentlemen, I have next to speak of *exostosis*. The term signifies a tumour of a bony nature growing upon and arising from a bone. Some confusion has been occasioned by the term having been applied by some authors to osseous swellings of various kinds—some of which receive this name merely because they are connected with bones. Thus, whether the enlargement be *spina ventosa*, that is, an expansion of the walls of a bone by suppurative within it, or whether it be a deposition of osseous matter between the periosteum and the surface of a bone, the effect of venereal inflammation; whether it be a fibrous or medullary tumour growing in the cancellous structure, and producing swelling of a bone, or whether it be really a bony tumour growing out of and arising from the walls of a bone; the term *exostosis* has been sometimes employed to denote each of these different kinds of disease. I need hardly say, that this has led to great confusion, and is a bad arrangement; nor has this confusion been at all diminished by the division of exostoses into *true* and *false*, the latter denoting *spina ventosa* and certain fungous and medullary tumours beginning in the interior of bones, and then making their way outwards. Sir Astley Cooper describes *exostosis* as having two seats; by *periosteal exostosis*, he means that form of the disease, in which bony matter is deposited between the periosteum and the surface of the bone; but, by *medullary exostosis*, he implies a growth from the medullary texture by which the bone is expanded and ultimately absorbed and destroyed, so that the tumour protrudes externally. Now, this latter kind of tumour does not consist entirely of bone, and some forms of it are believed by many pathologists to be of a malignant character, partaking of the nature of fungus hæmatodes, or medullary sarcoma. Sir Astley Cooper has also divided exostoses into *cartilaginous* and *fungous*, the former being preceded by a cartilaginous deposit, into

which osseous matter is afterwards secreted; while the latter is undoubtedly nothing more or less than fungus hæmatodes of the bones.

The largest *true exostoses* are chiefly met with on the long bones, and if you sometimes meet with considerable ones on other bones, they are generally not of the true kind: thus, in the *cartilaginous exostosis of the medullary membrane*, described by Sir Astley Cooper, the shell of the bone is extremely thin, and, within it, there is an elastic, firm, and fibrous substance. In other instances, you will notice a medullary substance, which medullary substance is known to have the same character as that of fungus hæmatodes; whereas, the fibrous growth is not of a malignant nature. It is universally admitted, that the blending of so many different diseases together under the name of *exostosis* creates vast impediment to a clear view of the subject; and, as far as I can judge, it would be much better if the term *exostosis* were limited to a bony tumour, growing out of a bone and forming a projection on its surface, and not consisting of the growth of a soft substance originating in the interior of the bone, leading to an expansion of its walls, and afterwards to a protrusion of the fungous, fibrous, or cartilaginous mass itself.

Various terms are applied to true exostoses, according to the textures which they exhibit; some are *lamellated*, there being distinct layers observable in their texture; others are *cellular*, and not solid; while others are so solid and hard, that they resemble ivory, and hence have been called *ivory exostoses*. Some are so irregular and angular, that they have received the name of *stalactitic* or *spinous exostoses*. Unfortunately, there are only two or three specimens of exostoses in this museum, and these have not been put on the table this evening. One of them, though small, is very complete: you shall see it, if possible, to-morrow evening.

Confining my remarks exclusively to *true exostosis*, I may observe, that such a swelling is always completely fixed and immovable, and, at first, is unattended with any pain or inconvenience; it generally comes on in a very slow and indolent manner, and sometimes it remains, for several years, nearly in a stationary condition. Indeed, it is generally some years before it produces much inconvenience, and then it may cause severe agony; and occasion considerable mischief by its pressure on particular parts. An exostosis of magnitude, situated behind the knee-joint, has been known to interfere with the action of the flexor muscles. The growth of an exostosis from the os pubis has by its pressure rendered the urethra impervious. An exostosis of the thigh-bone, though of small size, has been known, on account of its projecting angular shape, to obliterate the femoral artery; an instance of which occurred in the practice of Baron Dupuytren. An exostosis of the orbit has frequently produced a displacement of the eye. An exostosis of one of the lower cervical

vertebræ has been known to press upon and obliterate the subclavian artery. An exostosis, extending backwards from the lower jaw, has produced a fatal impediment to respiration, by its pressure on the larynx. We have, then, numerous examples of the dangerous consequences of exostoses in particular situations; indeed, the prognosis in this disease materially depends on the situation of the tumour, and the possibility of removing it, with due regard to the parts amongst which it is placed. I am here speaking of true exostoses; because others, of a medullary character, are entirely different diseases, the cure of which involves the question, how far it is possible to cure, or effectually remove, fungus hæmatodes by operation.

Unquestionably, gentlemen, the bones most liable to exostosis are, first, the femur; secondly, the humeri; and thirdly, the lower jaw. But exostoses are met with on the sternum clavicle, and the bones of the head; in short, I may state, that there are no bones on which exostoses may not be produced. All the bones are liable to the disease, though some more so than others.

The causes of the origin of exostoses are involved in considerable obscurity. It would appear as if there existed in some individuals a predisposition to the disease, exostosis forming, in such persons, from very slight and trivial exciting causes. A little while before I began my professional studies at St. Bartholomew's Hospital, there was a youth there who was sent out of Cornwall, and the particulars of whose case were always mentioned in Mr. Abernethy's lectures. In this individual, a trifling blow on any part of his body would invariably lead to the production of exostosis; and this disposition to form bony tumours was not confined entirely to the skeleton, for, after a blow on the muscles a sort of osseous deposition would take place in them; in fact, the margins of the axillæ had become ossified in this lad: the great pectoral muscle and the latissimus dorsi were both turned into bone at their edges, so that the patient was completely pinioned. I forget, at the present time, how many exostoses could be counted in the patient, but they were numerous:—the case was very extraordinary.

With respect to scrofula being concerned in the production of exostosis, I think it very doubtful, though it has been asserted by authors of reputation. I know of no good foundation for the doctrine;—exostosis and scrofula are sometimes co-existent, but this is probably an accidental coincidence.

As for the *treatment of exostosis*, I may at once tell you, gentlemen, that we possess no means of checking the growth, or preventing the increase, of a true exostosis. I have been sometimes consulted by patients for exostoses, and have tried, as a matter of form, blistering, mercury, and iodine preparations, but I never saw a case that was materially benefited by them. I was lately consulted by a lady, under

the care of Mr. Huntley of Staines: she has an enormous exostosis of the lower portion of the femur, and in that case blisters and iodine embrocations were tried, but without the slightest effect on the progress of the disease. The case which I am speaking of had been seen by Mr. Lawrence and other surgeons, but no treatment, that had been suggested, had proved serviceable. But you should remember, that sometimes exostosis leads to inflammation of the soft parts, and then you would of course employ common antiphlogistic plans, viz., local bleeding, cold evaporating lotions, aperient medicines, and perhaps the blue pill, or calomel with opium. You may relieve the inflammation in this manner, but, as for dispersing the tumour by the use of medicines, there is not the slightest chance of success. However, in many instances, surgery may yet be of essential service; for, though you cannot disperse the exostosis by external or internal medicines, you may, when it is producing dangerous effects by its pressure on neighbouring organs, saw it, or cut it away with one or other of the instruments, which I showed you in the last lecture:—the saws invented by the late Mr. Hey, trephines, and saws capable of working by machinery in deep confined spaces. Of course I mean that an operation is to be performed only when it can be done without danger to the neighbouring organs. In the operation, the first object is to make such a division of the soft parts as will enable you to get at the base of the tumour without difficulty. Of course there will be much difference in the facility of removing the tumour: its shape is one circumstance that will have influence: when its base is broad the operation will generally be difficult; but sometimes the base of an exostosis is narrower than its body, and then its removal may be easy. Even when you are not able to remove the whole of a true exostosis, you may sometimes do essential good by taking away a part of it; for this kind of bony tumour is not attended with any malignity, and meddling with it will not turn it into any dangerous variety of disease. In some instances, when it is not practicable to saw away the tumour, attempts have been made to get rid of it by purposely exciting a necrosis of it, by removing the periosteum from its surface. Three or four years ago, I was consulted by a woman who had an immense bony swelling on the face. As several medical practitioners suspected that it arose from a fungus in the antrum, a point on which I had doubts, I sent her to Mr. Lawrence for his opinion, who coincided with me, that it was an exostosis of the upper jaw-bone. Now, in this example, after vast suffering, and repeated inflammation, and abscesses of the soft parts, the bony tumour came away spontaneously: it was attacked with necrosis, and exfoliated. The tumour, which was very large, came away by considerable pieces at a time, and the woman is cured, I believe, with the exception of a good deal of

disfigurement of the face. This case should teach you not to be too hasty in resorting to operations for supposed fungous diseases of the antrum.

Recollect the possibility of an exostosis being got rid of by an accidental occurrence of necrosis, or by this being purposely induced by surgical means. An exostosis may be so situated that you cannot prudently attempt any operation upon it; for instance, it may be so near a large joint, that any attempt to remove it by a surgical operation, would lead to such an inflammation of the joint, as would not only endanger the limb but the patient's life.

In relation to exostosis, I might here mention a case, that is sometimes met with, where a considerable swelling of a bone arises from the formation of hydatids in the cancellous texture. In the *Medico-Chirurgical Transactions* of London, you may read the particulars of an interesting example of this disease. The tumour, which was in St. George's Hospital, under Mr. Keate, was situated on the cranium, and occupied the greater part, if I remember rightly, of the os frontis. It was not known at the time of attempting its removal, what was the exact nature of the swelling; but, on performing it, a collection of hydatids was discovered between the tables of the skull, and before they were completely extirpated, and the patient could be cured, repeated operations, and the application of the strongest caustics were necessary. The case, in my opinion, reflects great credit on Mr. Keate, by whose judgment and decision, a disease, so formidable, on account of its situation, was effectually removed.

Osteo-sarcoma is a term frequently employed, though rather vaguely; it is found to be a convenient name, because it suits any tumour, which consists partly of bone, and partly of a soft or fleshy substance: thus, the medullary tumour of bones, when surrounded by more or less osseous matter, has been sometimes described under the appellation of *osteo-sarcoma*. Other tumours, situated between the periosteum and the surface of the bone, also, sometimes, receive the same name. But, more commonly, the term is applied to a tumour that begins in the medullary texture, and assumes a fibrous or medullary character, and is afterwards blended with osseous matter, or the remains of the original shell of the diseased bone. When fibrous, it is not malignant; but, if you observe that it is of a soft pulpy nature, you may suspect it to be of the same character as medullary sarcoma. Of late, *osteo-sarcoma* is a word used so much at random, that it should either be discarded, or confined to a definite form of disease. The lower jaw is sometimes the seat of medullary tumours, which frequently begin in the canal mentalis, and after distending the bone, in an immense degree, they may dangerously obstruct deglutition and respiration. In some instances it is necessary to remove nearly the whole of the lower jaw, in order to free the patient from this malignant

form of disease. Tumours of a similar character sometimes grow from the antrum.

Gentlemen, I believe that I have now brought under your consideration all the principal diseases of bones, except scrofulous caries of the spine, scrofulous disease of the heads of bones, and some other cases, which do not come within this division of the lectures. *Spina bifida* also remains to be described, but as it is a disease that affects only one part, and not several, it will claim attention in a future lecture. To-morrow I will commence with the diseases of joints.

CLINICAL LECTURES.

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital, Oct. 22, 1833.

LECTURE VIII.

On Erysipelas Phlegmonodes.

GENTLEMEN,—I place on the table the histories of two cases of this disease, which have been taken by Mr. Foote with great care; you can read them at your leisure. The men you must know; I have thought it right to see them every day during the last week, and I hope you have done the same.

Deep-seated Abscess in the Thigh.—Super-vention of Erysipelas.

Samuel Sharpe, ætät 41, a lighterman, admitted October the 4th, 1833, under Mr. Guthrie. Says he is not accustomed to drink, but takes his two or three pints of porter in a day. About a week ago he discovered some inflammation and vesication on the great toe of the right foot, of which he does not know the cause. About the same time, he was attacked with a severe rigor, which lasted three quarters of an hour, and was followed by a second an hour and a half afterwards; has not since experienced any. Two days afterwards he discovered a redness, extending up the inside of the leg and thigh nearly to the groin, attended with fever, heat of skin, and great thirst; he consulted Mr. Ord, who directed him to apply a lotion of gin and water, and gave him some aperient medicine. The inflammation continued to increase, and four days after the commencement of the attack he could not leave his bed; the redness then disappeared from the leg, and appeared to be wholly concentrated on the inside of the thigh, about the middle third and did not spread higher than the groin. When he was admitted, there was not much febrile excitement; his appetite was good, slept pretty well, and the bowels were well open; there was an evident tumefaction of the thigh at the inflamed part; the integuments presented a rose-red hue; he complained of a feeling of weight in the limb, and

pain (deep seated) on pressure, which gave a doughy oedematous feel; sensation of deep-seated fluctuation; no inflammation of the leg and groin; is not in pain, except in the thigh; pulse full, strong, and frequent, 100; skin warm, and bedewed with perspiration.

5th. Mr. Guthrie saw him to-day, and made an incision with a scalpel, which he afterwards enlarged with the assistance of the director; about an ounce and a half of pus was evacuated; linseed meal poultice.

R. Magn. sulph. ʒij,
Liq. ammon. acet. ʒij,
Vin. ant. tart. ʒss.
Mist. camph. ʒij.

m. Fiat mist. cuius capiat cyathum vinosum bis in die.

6th. Had a bad night, but he says he is now much better, and nearly free from pain; there is considerable discharge; the incision relieved him very much. Continue.

8th. Discharge considerable; no pain or inflammation, except about the wound.

10th. Continues to improve.

15th. The lips of the incision are brought nearer in apposition by strips of adhesive plaster.

17th. Healing, wound contracting.

19th. A patient, with erysipelas phlegmonodes of the left arm, was placed in a bed immediately next to his on the 16th. He (Sharpe) has now an attack of erysipelas, chiefly affecting the neighbourhood of the wound; the margin of the tumefaction is well defined, as is also the termination of the inflammation; there is some fever present; is in great pain; hot skin; tongue covered with a dirty brown fur; pulse quickened and frequent, rather hard, 100; bowels open by medicine; ordered a poultice over the parts inflamed; omit the plaster; purge and starve. Mr. Guthrie saw him afterwards, and directed that if it continued to spread, the argem. nitrat. should be applied to arrest it.

R. Pulv. jalapæ gr. x,
Hyd. submur. gr. iij,
M. fiat pulv. statim sumend. repetend
in 6tis horis si opus sit.

20th. Had a good night; had both the powders, and the bowels open in consequence; the erysipelas is spreading inferiorly; pulse quick, of moderate strength, 86; tongue covered with a white fur, and moist; skin moist; thirst diminished; not much pain; the arg. nitrat. was not applied. Mr. Guthrie made an incision about two inches long in the lower part of the inflammation, and allowed it to bleed, by which about an ounce and a half of blood was drawn; ordered to continue the poultice, and have a dose of his mixture.

21st. Was not able to sleep much during the night, but was not prevented by pain; the erysipelas is extending upwards; bowels open freely; tongue covered with a white fur and moist; pulse throbbing and rather strong, 90. The arg. nitrat. was rubbed in a circle

over the upper parts of the thigh. Pil. cathart. ij.

22nd. Passed a good night; bowels open by medicine; tongue furred; feels easier; the part where the caustic was applied has not a black, but rather a brown, colour; no vesications on it; the erysipelas is not extending; discharge from the first incision continues.

Erysipelas Phlegmonodes.

James Coneybear, ætat. 31, was admitted Oct. 16, 1833, into John's Ward, and placed in a bed adjoining that of the preceding patient; is a stone mason by trade. About ten days ago he wounded the integuments covering the metacarpal joint of the middle finger of the left hand; the same evening, the hand began to swell, and became hot and painful, and very red; the wrist became stiff, so that he could not use it. The next day the inflammation spread up the fore-arm, and he sought surgical advice. He had cathartic medicines, and was ordered to foment the limb frequently; he was then the subject of considerable fever, and could not sleep; he considers that he was relieved by the measures adopted, but the arm still continued to get worse, in regard to the tumefaction, until he applied on the 16th; the pain had been less for the two days immediately preceding; the fomentations latterly were changed for linseed meal poultice, and he has had two applications of leeches, twelve each time. When he was brought into the surgery, the fore-arm and arm appeared to be swelled to three or four times beyond the natural size; the whole of the limb is covered with a dark erysipelatous inflammation, extending up rather beyond the middle of the arm, where it ends abruptly, and the fore-arm covered with vesications of a considerable size; there is considerable tension, and the swelling pits on pressure; the pain is not very great at present; skin hot; tongue covered with a brown fur, and dry; pulse full and rapid; bowels open; no headach; thirst; has not experienced any rigors. A sensation of deep-seated fluctuation was considered to be present, and consequently an incision, about two inches long, was made on the inside of the fore-arm, through the fascia, but there was not any pus; the cellular tissue was much thickened, and appeared to be dead; two small arteries were divided, and bled freely; one required a ligature; from these about six ounces of blood were lost; several other incisions were made through the integuments of the fore-arm, but none deeper, one on the posterior surface of the limb was of considerable extent; he was then sent to bed, put on low diet, and ordered to have the whole limb enveloped in a poultice.

R. Conf. aromat. ʒij,
Ammon. subcarb. ʒj,
Mist. camph. ʒviiij.
Fiat mist. capiat coch. ampl. ij, tertius
horis.

17th. Passed a good night; febrile symp-

toms continue; heat of skin, especially of the inflamed arm; tongue not cleaner, and still continues dry; pulse full, but not so rapid, 96; urine scanty and high coloured; no head-ach; bowels not open; not much pain; no discharge; cellular tissue sloughing. Another incision was made on the inside of the fore-arm, and one on the arm, to relieve the tension, which still existed; nothing else, it was remarked, would prove of service in such a case; ordered pil. cathart. ij, statim et haust. cathart. postea, omittit mist.; beef tea, double strength.

18th. The incisions were practised yesterday evening, each of them three inches long; the cellular tissue beneath is evidently sloughing; the arm looks less tumefied, and is paler; the brown fur on the tongue is now in the centre only; continues dry; bowels moderately open; and he says the stools are not offensive; pulse regular and of moderate power.

19th. Arm much swollen; pulse improving and quieter; bowels open; there is a small opening, where the original cut was on the back of the hand, from which pus can be pressed out; a director was passed in towards the wrist, and the integuments divided; the incision on the fore-arm, which was mentioned as of considerable extent, but not passing through the cellular tissue, was freshened and made deeper, some pus was thus evacuated; skin moist, and is altogether improved.

20th. Passed a night tolerably free from pain, sleeping occasionally, but not uninterruptedly; says he has not pain, but rather an aching sensation in the arm; tongue continues furred, but is rather moister; urine still scanty and high coloured; skin moist; pulse regular, but not full, quieter, 84; bowels not been open to-day; thirst lessened; appetite improving; less tumefaction of the arm, but the fore-arm and hand are much the same; discharge trifling, of a thin yellow appearance. Continue.

21st. Passed a bad night, but not from pain; suppuration greater from incisions; suffers from burning pain in the limb; has not had any rigors. Mr. White saw him this morning, and objected to the linseed poultice, the whole advantages of which he thought would be obtained by simple dressings on the incisions, and fomentations over the whole limb, without its weight; matter was found to have formed in the space between the metacarpal bones of the thumb and fore-finger, both on the back of the hand and in the palm, the two communicating; an incision was made on the posterior surface, and about an ounce and a half of pus evacuated; bowels freely open; tongue covered with a yellow coat, but not so dry; pulse regular and moderately full; the thirst lessened, and appetite improving.

22nd. Passed a better night, and had four hours' uninterrupted sleep; feels easy and continues to improve; pulse good; bowels open; had two opening pills last night; tongue as at last report; says the fomentations are more agreeable than, and not so heavy as, the poultice; arm protected by a fracture cradle.

Having thus shown you the advantages of a particular mode of practice, let me refer you for a concise history of the progress of this disease to my work on Gun-shot Wounds; you will there find the practice, first recommended by Mr. Hutchinson, of making short incisions, and my deviation from it in favour of longer ones. Be pleased to read from page 99 to 111, but particularly from 106 to 111, as follow:—

“In many cases the inflammation and subsequent suppuration are in no degree circumscribed, the cellular membrane sloughs in the whole circumference of the limb, the skin being undermined loses its vitality, and the consequences are often very distressing, and not unfrequently fatal when the treatment is undecided.

“Mr. C. Hutchinson, in his Practical Observations on Surgery, has the merit of recommending a new mode of practice, by incision into the inflamed part at an early period, which, in most instances, arrests the progress of the disease. His observations were not, however, at first received with that attention they deserved, more perhaps from the term *erysipelas phlegmonodes*, which he retained as the name of the disease, than from any other cause. Since that period this complaint has been more generally called *diffused cellular inflammation*, or *erysipelatos inflammation of the subcutaneous cellular membrane*, which is sufficiently characteristic of the seat and of the nature of the disease. If the simple term *erysipelas* be confined to an affection of the skin, no difficulty can occur in distinguishing these complaints, and error will be avoided in regard to the practice which is essentially necessary to be pursued.

“This species of inflammation is usually the consequence of injuries; the skin assumes the erysipelatos tint, although it is in general something more of a brighter colour. The part swells more rapidly, does not admit of the impression of the finger being made with the same facility as in either common erysipelas or in the œdematous inflammation, and does not retain the mark in the same manner. There is clearly a thickening of the parts beneath the skin, which is also evidently on the stretch, is very tense, and therefore glistening. The pain is considerable. It is not, however, either or the whole of these symptoms which attract particular attention; it is the rapid depression and derangement of the nervous system. The altered and subdued appearance of the patient from the previous day, his hurried manner, the quickness and irritable state of the pulse, the foulness of the tongue, heat of skin, and towards night a state of wandering or delirium, indicating the extent of irritation. If relief be not obtained, the swelling extends

Note by the Reporter.—Nov. 18. Sharpe has been discharged cured, and Coneybear is nearly well.

along the whole limb, the skin becomes of a darker colour, the erysipelas affecting it passes beyond, and is the precursor of the inflammation of the subcutaneous tissue; the distinction between them is well marked and cannot be mistaken. The firmness of the part first affected has by this time yielded in some degree; its resistance, or elastic feel, is less evident; and it has obtained a springy, fluctuating feel to the touch, which is peculiar, and which it has acquired before any matter has formed. On making an incision into the part at this period, the cellular tissue will be found to have changed its characteristic for a gelatinous appearance of a light leaden colour, which it obtains from the deposition of fluid into its cells, nearly in the act of being converted into pus. The septa composing the cells have not, at this period, lost their life, and the fluid does not at first exude, as it will be found to do a few hours later, when the matter deposited has become purulent. When this change has taken place, the patient is obviously in the greatest danger; and if the cause of irritation be not removed or alleviated, he will, in many instances, die under the most marked symptoms of irritative fever of a typhoid type.

"When the powers of the constitution are equal to sustain and resist this state of disease, relief is obtained by the sloughing of the skin and the discharge of the matter beneath. The skin is, however, exceedingly tough, and before it yields and dies, the fascia beneath the cellular membrane is often destroyed, and the muscles are implicated and exposed. Mr. C. Hutchinson thinks 'pus is seldom formed in the substance of the adipose part of the tela cellulosa exterior to the aponeurotic expansion, that is, between the membrane and the skin; its most common position is beneath these parts, and in immediate contact with the muscles.' This opinion does not accord with my observations; the sloughing of the fascia and the formation of matter beneath being most frequently caused by the continuance of the disease, and rarely occurring when the proper method of treatment has been adopted.

"Mr. Hutchinson recommends several small incisions to be made, about an inch and a half in length, and from two to four inches apart, varied in number from four to eighteen, according to the extent of surface the disease is found to occupy. I have found one or more longer incisions answer equally well, and they appear, in many instances, to be preferable, giving more decided relief, as one incision can sometimes be made so as to be very little remarkable, whilst several smaller ones occasion more deformity. On making an incision at an early period, the leaden coloured and slightly gelatinous appearance of the cellular membrane will be readily perceived, and the state of the tension of the skin will be estimated by the retraction of the edges of the wound, one of four inches in length, separating two in width. Sometimes a con-

siderable quantity of blood will flow from the divided surface, but this will in general be greater if the incision be carried through the fascia, which is seldom necessary at an early period of the disease. If the operation has been delayed until the springy fluctuating feel, communicated by this gelatinous state of the cellular membrane, be changed into the more marked feeling which is communicated to the foot when stepping on a bog or quagmire, the cellular membrane will have been destroyed, the skin will have been undermined, a part of it must be lost in spite of the operation, which will only be in time to allay the constitutional symptoms, and thereby perhaps save the patient. I attribute these violent constitutional symptoms, not to the formation of matter, or the sloughing of the cellular membrane, but to the stretching and over-excitement of the skin when in a state of inflammation, caused by the swelling of the parts beneath; whence the relief obtained from the incisions.

"This opinion seems to be confirmed by the fact, that the constitutional symptoms subside, and the patient is placed in safety, although the incisions should not have been made until after the whole of the cellular membrane had passed into a sloughing state, and which process must be afterwards completed, and the parts separated before the cure can be accomplished. The following case is so striking an instance of the efficacy of long incisions, and of their capability to remove the greatest constitutional irritation, that I do not consider it to be necessary to adduce more. Thomas Key, aged 40, a hard drinker, admitted into the Westminster Hospital, as an accident, on October 21, 1823, at night, and under my care in consequence of falling and striking his left arm against a stool four days previously, which had given rise to erysipelatous inflammation. He was smartly purged with calomel and jalap, on his admission, which was followed up the next day by small doses of the antimonium tartarizatum, and sulphate of magnesia, so as to cause both vomiting and purging.

"In the evening he lost ℥xxv . of blood from the temporal artery. The arm was very much swelled, the skin of erysipelatous redness, very tense, elastic, springy, and yielding a sensation of fluctuation, the inflammation being evidently deep-seated; pulse, 120, strong; tongue dry and furred; great thirst; skin hot; is very restless, unruly, and wandering. After the bleeding he became quiet, a profuse perspiration broke out over the whole body; he appeared relieved and comparatively tranquil. Fomentation and poultices were applied every three hours to the arm. On the 30th his state not being improved, a consultation was held to determine on the propriety of making incisions into the inflamed part; but this was considered improper by the parties consulted, and saline medicines with small doses of tinct. opii were substituted.

Oct. 31. Pulse 130; he is weaker, and more

irritable; was delirious all night; countenance sunk; skin hot and dry; tongue furred; was altogether in a state of extreme danger. The arm greatly swelled, of a darker colour, and giving to the touch a strong fluctuating boggy feel. I made two incisions forthwith into the fore-arm; one on the back part eight inches in length, the other five inches long on the under edge in the line of the ulna down to the fascia, which was in part divided, and one vessel bled freely. There was not any matter beneath it, but a considerable quantity of serum and matter of a gelatinous appearance was discharged, mixed with venous blood, but no pus. The incisions did not give much pain.

"Nov. 1st. Pulse 90, and steady; tongue furred, but rather moist; heat of skin moderate; slept occasionally during the night, and was much quieter; says himself he had a good night. The arm is less swelled; the cellular membrane is evidently sloughing, and this state extends beyond the extremities of the incisions on the back of the arm, which was therefore augmented to the extent of eleven inches. Ordered to continue the saline mixture, four grains of calomel and four of extract of colocynth, and the infusion of senna and salts to be given afterwards, and repeated until a due effect is produced.

"From this time he gradually recovered, the incisions were made, however, too late to prevent the loss of a considerable quantity of cellular membrane and skin. When a deep-seated erysipelatous inflammation takes place below the fascia of a limb, the whole extremity swells, it becomes firm, heavy, of a dull whitish colour, and is scarcely affected by the erysipelatous blush; is painful, and rapidly destroys the powers of life; the patient sinks unconscious of his danger, when he fancies himself relieved. The appearance of the part on dissection very much resembles that noticed page 97. It is a fatal termination by no means uncommon in persons of a bad habit afflicted with erysipelatous and gangrenous inflammation, or sloughing abscess in the neighbourhood of the rectum."

I am not aware, gentlemen, that after the lapse of ten years—and it is exactly ten years since the man was admitted into this hospital, whose case is the first on record of long incisions being made for the cure of erysipelas phlegmonodes—that I can give you a better, or a more compendious history of the disease, and of its treatment, than I have just read.

It is I think impossible for any one to read it and not give me the credit, if there be any attaching to it, of having introduced this practice. Mr. Lawrence, in his paper on Erysipelas, published in the 14th volume of the *Medico-Chirurgical Transactions*, says, "Mr. Guthrie has found that one or two long incisions accomplished every useful purpose, and has therefore adopted that plan." He should have said, and "therefore introduced this practice, which I have since adopted," or words

to that effect. I have no doubt of his taking the first favourable opportunity of doing this, for as my case of Thomas Key occurred in October, 1823, and is to this moment the most decisive case on record, whilst Mr. Lawrence's first case occurred in the summer of 1825, and his paper was only read to the Society on the 9th of October, 1827, whilst my book was published the 18th of June, 1827, the priority is as clear as it appears to me it is indisputable. The first and indeed all the credit is due to Mr. Copland Hutchinson, the second degree of it, if there be any, and a mere improvement, is due to me. They are both useful, and perhaps only both really applicable to particular stages of the complaint.

I am aware that the practice of incisions is, with some surgeons, still a questionable matter; it appears to me to be as easily reconciled and regulated as any other in surgery. I shall endeavour to draw some conclusions for your guidance.

1st. Ascertain that you have the proper kind of erysipelas before you. If you are not certain of that, read four pages, 106 to 111 of my book on Gun-Shot Wounds, or any better one you may have at hand, and you will not make a mistake.

2nd. Consider well the stage of your disease. In the early stage a small incision, of one inch or one and a half, will suffice, and at this period a gelatinous appearance of the cellular membrane, of a light leaden coloured hue, will be alone observable, but if the cellular membrane be yellower, or full of pus, sloughy, longer incisions will be indispensable, in order to allow the skin, thus divided, to retract and to take off the tension, the irritation of which is the cause of the deadly sympathetic fever, and also to give free vent to the discharge.

3rd. The length of the incision must depend then on the state of the part. I have heard of incisions being made twenty-three inches in length, but I have never made one longer than eight, and that in the case of Thomas Key. I think that in general, from three to four or even eight inches will be sufficient, and they may be repeated, if necessary, in different places.

The practice thus recommended to you has been, I believe, exemplified in the two cases you have seen treated. In one a short incision, from one inch and a half to two inches, sufficed to arrest the disease. In the other seven incisions, of from three to four inches in length, were absolutely required in different places, from the back of the hand to the middle of the upper arm. This man tells you he feels he must have died if it had not been for the relief he obtained from the incisions. I know that he would, from having seen many, very many, do it.

It is the more gratifying to me, gentlemen, to bring this case before you, because it has been treated by your house surgeon, Mr. Finch. The patient applied on Wednesday afternoon, and Mr. Finch, by his immediate incisions, saved his life. I encouraged him to

proceed, but I have only, like you, been a spectator ;—he was not under my care ;—I hope you, gentlemen, have been as attentive a looker on as I have been.

LECTURES
ON THE
PHYSICAL EDUCATION AND DISEASES
OF INFANTS AND CHILDREN,
BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE X.

Bad Effects of Cold on Infants—Necessity of Warm Clothing—Natural Alimentation—Maternal Lactation, or Suckling.

GENTLEMEN,—At our last meeting I described the first clothing proper for new born infants, as the influence of the atmosphere on their skin is capable of producing a great number of diseases. The skin has infinitely more sensibility than that of the adult, it approaches more nearly to that of mucous membrane. Its sympathetic relations with the brain, as well as with the whole mucous membrane, are the most intimate ; and therefore it is imperiously necessary to protect it from the disagreeable and irritating effects of the air, or cold. The infant has left a high temperature, and care must be taken to preserve a proper degree of warmth in the apartment in which it is to be washed, dressed, and nursed. The bad effects of cold on the human body have been long known to physicians as the exciting causes of a host of the most fatal inflammations and fevers. "Half of mankind," says Ritter, "perish before the close of the third year ; and there is no disease, not even of the nails, hair, or bones, that it may not occasion." There is no doubt that a much greater proportion of the children of the poor than of the rich, perish before the fifth year ; and this mortality is principally caused by exposure to cold, and also by the administration of improper aliment.

Cold acts most powerfully upon the skin and mucous membranes, and the best preventive to its influence is warm clothing. This is well known to medical practitioners, and is singularly attested by Captain Parry, who states that at a temperature, 30° below zero, on Fahrenheit's thermometer, the mucous membrane of the respiratory apparatus escaped injury, when the body was kept properly clothed.

The air causes a disagreeable impression upon the very sensitive skin of a new born infant, because it is of a much lower temperature than that in which the infant lived before birth. It is therefore necessary to recollect this during the first days of life, and place the infant in bed with the mother, especially in cold weather, as she will protect it from cold by a kind of incubation, and preserve it in a degree of heat nearly equal to that which it has lately enjoyed. It should be gradually

habituated to the action of the air, at first warm, and after a few days, cold, but it is highly imprudent to expose it suddenly to atmospheric vicissitudes, because we should accustom it by degrees to support the alternations of heat and cold, of dryness and humidity, to which it will finally be exposed. In cold weather the infant should not be removed from the lying-in-chamber before the expiration of the first month of its age.

The productive faculty of caloric is at its minimum in the first ages of life, and is too feeble for the animal temperature when exposed to intense cold. MM. Milne Edwards, and Villermé have proved that the mortality of new born infants is much greater in the colder provinces of France, and that the greatest number of deaths in the whole country take place in the coldest months. They think that this conclusion deserves the attention of legislators and ministers of religion, and they prove, by numerical results, how extremely dangerous it is to expose new born infants to the action of cold in conveying them for baptism, and they inquire would it not be better in winter to avoid cold affusion. They also object to transporting infants on the third day after birth for inscription at the public registers.—Acad. des Sciences, Feb. 1829. Dr. Trevisan has instituted similar researches in Italy, and arrives at the same conclusions :—1. In Italy, he states, that of 100 infants, born in the months of December, January, and February, 66 died in the first month, 15 in the course of the year, and 19 survived. 2. Of 100, born in spring, 48 lived longer than the first year. 3. Of 100, born in summer, 83 survived beyond the first year. 4. Of 100, born in autumn, 58 survived the first twelve months. He ascribes the mortality to the practice of conveying the infants, a few days after birth, to the church for baptism ; and he agrees with MM. Edwards and Villermé in requiring from the ecclesiastic authorities proper measures for the prevention of such disasters, without in any way opposing the precepts or practice of religion.—*Annali Universali di Medicina*, tom. xxxv.

The affusion of cold water on the head of a new born infant causes pain and irritation, as is proved by its screaming during baptism. The mortality produced by both these causes, which was aggravated by the previous exposure to cold, was so forcibly demonstrated by Azviani, Mauriceau, Brouzet, and others, as to induce the Prince Bishop of Wurtzburg, in 1790, to command his clergy to baptize at the houses of their parishioners during the months of December, January, and February, and when the weather was cold to employ tepid water.

The directions of M. Ratier are so excellent upon this part of the physical management of infants that I must copy them : "every day, after the infant is washed, it should be left naked for a few minutes, so that it may stretch and move its feeble limbs, either under the rays of the sun or before a clear fire ; the

mother at the same time making slight frictions all over the surface of the body, which will greatly excite the skin and favour insensible perspiration. It is proper to keep the cot or cradle removed from currents of air, but should its coverlet be too thick or too close it has a double inconvenience of impeding the renovation of the air, of concentrating heat too much, which, mixing with animal exhalations, becomes the source of many diseases. When the infant can walk, it will be more necessary to expose it to a free air, because henceforth it will be less under the surveillance of the mother, and has more need to be hardened against atmospheric vicissitudes, to which it will be imprudently exposed." This exposure is necessary as age advances, because man is not destined to be imprisoned in confined and unwholesome air. An elevated situation is preferable for infants, because the air is dry and frequently changed; and hence low damp situations are objectionable, more especially when the air is impregnated with emanations of animal and vegetable substances in a state of decomposition, or putrefaction. The best situation is that in which the air is frequently renewed, ventilated, and warmed by the rays of the sun. Therefore the country air is preferred. It is advisable to have nurseries elevated, with their cross-barred windows to the south or east. These should be opened in the morning and closed only at night, except in cold and humid weather. In winter it will be necessary to preserve a warm temperature, but we must not recommend too much heat, which would render the infant liable to cold and especially to inflammation of the chest; while the contrast will be too great between the interior and the exterior temperatures. It must be evident to every rational individual, that exposure to sudden transitions of temperature in summer or winter is highly dangerous to adults, and much more so to infants and children, and therefore we should caution mothers and nurses against the practice of exposing tender and delicate children to the open air in cold or inclement weather, without very warm clothing. A child in a nurse's arms makes very little exertion, does not increase the circulation of the blood by motion or exercise, and will be much more affected by cold than a grown person. Thousands of children are annually destroyed by the practice of exposing them to cold in damp weather. It is, however, better for the health of an infant to be exposed to a slight degree of cold than to too much heat, more especially when it begins to walk, and is properly clothed.

Practitioners justly inveigh against too much warmth, which would irritate the skin, predispose to cutaneous diseases, affections of the bronchial and intestinal mucous membranes, and eruptions on the head. In Poland the head is kept very warm, and hence the origin of the disease denominated *Plica Polonica*, which is unknown in Italy and all countries where the head is uncovered. It is also inju-

rious to tie strings under the chin too tightly, as this practice impedes deglutition and respiration. The head should not be kept too warm; and when the hair is sufficiently grown no other covering is necessary. It is improper to expose the head to the rays of the sun when ardent. It is right to mention here, that the hair should be washed and combed twice a-week, to prevent irritation, water in the head, and various eruptions. I have already stated that the dress should be loose, so as to admit of the free motions of the superior and inferior extremities, as well as of the chest and abdominal parietes, and should be secured by tapes instead of pins. Dr. Underwood relates a case of a child who died of convulsions. The medical attendant was unable to account for the cause of the disease; but the body being stripped, a pin was found forced through the anterior opening of the head into the brain. The sensibility of the infant's skin is excessive; and hence we often see cases, in which an infant is screaming or convulsed from the prick of a pin, or the bite of an insect.

About the third month, it is usual in this country to put on short clothing. As soon as short clothing or habiting is adopted, the head should be kept cool, the body and limbs as warm as possible, especially in cold weather. When short clothing is put on, the hands and feet ought to be covered with woollen socks and gloves, and the neck surrounded with a boa, or "muffer" of swan's down, particularly when the infant is exposed to the open air. These precautions will prevent enlargement of the glands of the neck, chilblains of the hands and feet, and tedious abscesses, which, when opened, do not heal for a long time, but leave cicatrices or unseemly scars; disease of the joints, enlargement of the head and abdomen, rickets, and deformity of the spine and extremities. These diseases are extremely common among the children of the poor. In a variable climate like this, the dress of infants should always be suited to the weather, varied so as to produce warmth, and sufficient to obviate the bad effects of cold. It is often necessary to put on winter clothing in spring and the end of autumn, when the weather is inclement; and there is no greater error in the management of children, than in exposing them to cold for the purpose of "hardening them," as it is termed. They are sent out in all kinds of weather, and exposed for hours to extreme cold by nursery maids, who stand or sit gossiping, until the unfortunate little objects committed to their care are so chilled, that the inflammations already alluded to are frequently induced. To obviate this great evil, the nurse or child's maid should continue to walk and keep the infant in motion or exercise as much as possible, by changing it from one arm to another or dandling it occasionally. When she feels fatigued she should rest herself in some house, and not sit down on hall-door steps, or on the

grass, which is the usual custom. She should remember, that even a full grown person cannot well bear intense cold, while it would chill a tender infant almost to death. The great mistake made by those who have the management of children is, that they do not duly appreciate the delicacy and weakness of the infantile constitution, which they treat as they do their own. The physician always bears the difference of constitution in mind, and lays down particular precepts for the hygiene of different ages. The slightest reflection will convince every rational individual of the validity of our conclusion. The peculiarities alluded to have not escaped the ancient poets :—

"Ætatis cujusve notandi sunt tibi mores,
Molibibusque decor naturis dandus et annis."

Cold is a prolific cause of diseases; every part of the body may be inflamed by it, and most persons ascribe their complaints to it. Daily observation proves the truth of this position. We find ophthalmia, catarrh, tooth-ach, face-ach, sore throat with or without cough, swelling of the glands of the neck, cough, inflammation of the lungs, bowels, liver, abdominal viscera, joints, arms, trunk, and lower extremities, caused by it. If cold can produce so much mischief in the strong constitution of the adult, how much more dangerous must it be to that of the delicate infant, whose powers and constitution are so much more feeble. It is very surprising how few parents there are, who properly estimate the truth of this opinion. Few, indeed, have correct views on the helplessness of infants. Medical practitioners only entertain rational sentiments on the subject; they bear in mind the extreme delicacy of the infantile constitution so beautifully described in past ages :—

"Editus in lucem jacuit sine viribus infans."

"Tum porro puer (ut sævis projectus ab undis
Navita), nudus humi jacet infans indigus
omni,

Vitali auxilio quum primum in luminis oras
Nixibus ex alvo matris natura profundit,
Vagitum locum lugubri complet ut equum
est,

Cui tantum in vita restet transire malorum."

I should not quote from the classic writers so frequently, were it not essential to you to be well acquainted with the learned languages, in which most of you will be examined hereafter.

The choice of air is a matter of great importance in the rearing of children. It is unnecessary to dilate upon the salubrity of the air of the country, or on its superiority to that of crowded cities. In all cases in which circumstances permit, it would be better to bring up children in the country than in cities. But, in all circumstances, the most dangerous forms of cold are to be avoided, and these are, damp, foggy, and frosty weather, damp cloth-

ing and apartments, and currents of air. The bad effects of these are prevented by warm clothing, exercise, and a moderate use of wine, or ardent liquors in cases of adults. No matter what may be the season, our dress should be sufficient to protect the body from the injurious effects of the weather. If this precept be attended to, it would be proper to expose infants about noon to the open air, provided those who have the care of them keep walking and changing the position of their little charge. As a general rule, it is improper to expose young infants to the open air, early in the morning or late in the evening.

It is very dangerous to place young infants in currents of air or draughts, as they become affected with catarrh, or inflammation of the lungs, or in popular language, they take cold; their nostrils become stopped, they cannot suck, their sleep will be disturbed, and deprived of proper aliment and repose, they emaciate rapidly. When the head is "stopped," there will be catarrh or "snuffles;" and these may be in some measure obviated by keeping the infant in a warm temperature for some days, and avoiding to expose it to the open air. When it cannot breathe through the nostrils, it cannot suck; and this inability may be removed by dropping almond oil into the nostrils.

I cannot too forcibly observe, that the incautious exposure of young and tender infants during the first three months of their existence to cold, or rather cold air, may be rapidly followed by inflammation in any organ or part of the body. The commonest observer is aware, that all young animals are injured by cold, and so is the human offspring.

The next organ to the skin in activity, is the stomach, and its action on the aliment or food converts it into nutriment for the development of the whole body. The infant is voracious, because nature has to expedite its growth to manhood or womanhood. It requires a frequent supply of aliment, and when satiated, it falls into a tranquil sleep, because its wants are supplied and it is unable to take interest in surrounding and less important objects. In the first days of its life, it does nothing but eat and sleep; and this leads me to notice the source of its nourishment.

Maternal Lactation—Suckling—Nursing.
—The completion of delivery does not terminate the physical affinity, or natural connexion, between a mother and her infant. In a short time after this event, the blood that supplied the enlarged womb while it nourished the fœtus, now flows to the breasts, distends them, and forms the secretion of milk. This is as essential to the women as to her infant; because it prevents those child-bed fevers and inflammations which often destroy life. It is destined by the Divine Author of nature for the nourishment of the offspring, as the mother is the only source capable of furnishing the infant with the first milk, which is incontestably the best food fitted to the organs of

the new being, because it is the product of that body, of which the infant, a few moments before, formed a portion. The secretion of milk diminishes the susceptibility now existing to many child-bed diseases, and nothing is so proper for the preservation of the fullness, firmness, and beauty of the breasts, though the contrary is generally imagined.

The first milk, called *colostrum*, possesses aperient properties, and purges the infant of the dark contents of its bowels, denominated *meconium*. It is also a fact, that there exists between the growth or nutrition of the infant, and the increasing quantity of the milk, an exactitude of progression, seldom observed in other instances; in truth, there exists between the constitution of the infant and the mother, an intimate relation, so that the wants of the one are supplied by the other. Hence theologians, philosophers, and physicians, have universally agreed, that maternal lactation, or suckling, is an obligation on all healthful women, which cannot be dispensed with. Analogy confirms the truth and validity of this conclusion, because all mammiferous animals, that is, all which give milk, suckle their young, and none others. "Never," says M. Virey, "have the lionesses or panthers refused their udders to their young: it is the reverse with woman,—not the poor woman, who is excusable on account of her misery, who acts so unnaturally, but the rich one, who is surrounded by all the advantages and blessings of life. What does it matter, that her son should perish, provided that she may enjoy her pleasures? It is to the peasants that the vulgar cares of maternity appertain; the lady of fashion has other occupations."

Yes, the affectionate peasant mother takes nature for her guide. She sees every genus of the winged tribe bewail its lost young, how the parent heifer, when her calf has been taken away, wanders in every direction, fills the air with her lowings, and returning to her shed at sunset, still mindful of her offspring, she weeps (*grandibus ora riget lachrymis*), nor does she care for the limpid stream or rich pasture. She hears with how much bleating the pensive sheep seeks for its absent lamb, and beholds it, having in the evening a distended udder, delighting in its offspring; she wonders how, amidst a thousand lambs, similar in colour and voice, the mother knows its tender progeny, and how it knows its parent. The humble cottager, seeing all these examples everywhere around her, considers it unlawful for woman to yield in love to the lower animals. These will not suffer even the young of their own species to approach them; while women of the higher class society, violate the institutions of nature. It is in the humble cottage that the rustic infant is nursed with the happiest effects. The mother will not permit a strange bosom to nourish her issue; she rejoices to convey her health and her pure morals with her milk to her offspring, which receives the sweets of home, and wishes

to return to its affectionate mother its naïve, incipient embraces, and to know, by the applauding smile, its father returning in the evening, whose wearied limbs it fondly embraces. But the child, born under a gilded roof, is forced to change its household gods and go into sad exile; its unnatural parent throws off the mother at its birth, she transfers it to another, and she allows a dog to suck the breasts she denied to her child. After some years, she receives it, deformed and distorted, and it knows her not. On the other hand, the pious villager fondly cherishes her infant, and she is surrounded on all sides by her tender little ones, whom nature had abundantly nourished with milk. Felicitously has a great poet observed,—

"O fortunatos nimium sua si bona norint
Agricolæ"

Women in the higher ranks intrust the nurture of their offspring to heartless strangers, who can never supply the sustenance or the maternal care of a parent, who may communicate various diseases, or induce many by their neglect or ignorance, such as scrofula, rickets, deformities of the spine and limbs, syphilis, &c. &c.

The new born infant, as already noticed, requires a thousand cares, sympathies, solitudes, which can only be exerted by the mother's love and affection. No woman, worthy of the sacred name of mother, can refuse that feeble helpless being, to which she has given existence, that care and nutriment which reason, instinct, and nature, dictate for its welfare. It is perfectly impossible to procure as proper and wholesome aliment for an infant, as the mother's milk; for that of every other woman is at best, but a bad substitute. This must be obvious, when it is recollected, that no two constitutions are alike. Maternal lactation is ordained by nature, it is a part of generation, it prevents diseases, and is a bar to pregnancy, for it would be injurious to the woman as well as to the development of the infant, that conception should recur before the latter was capable of enjoying an independent existence, while frequent pregnancies would enfeeble the mother.

Lactation or suckling is a duty imposed on the human female by nature, for the preservation of the infant. In general the breasts enlarge in the last month of pregnancy, often secrete milk even before delivery, and in a majority of instances in a day or two afterwards. The augmentation of the precious fluid in two or three days after delivery, evidently proves that it is destined by the Author of nature for the nourishment and conservation of the new-born infant. It is the most appropriate aliment for the infant, as it is supplied from that body, of which the new-born being was so lately a part. It is superfluous to show the superiority of maternal lactation to every other means of nourishing infants. All women in the prime of life, and in good health, should

suckle their infants, and those in bad health should avoid this duty. There are two important precepts to be followed with regard to lactation; the first is, not to suckle the infant too often; and the second, not to suckle too seldom. In the first case, the infant will have habitual indigestion, hiccup, flatulence, griping, vomiting and diarrhoea; and in the second, it will become debilitated, while the stomach, being irritated by hunger, may become inflamed. It is difficult to lay down a rule as to the application of the infant to the breast. Desessartz thinks the following signs indicative of the hunger of the infant. "When the infant is hungry, it fixes its eyes on the nurse, they follow her every where, and it appears chagrined when she is at any distance; it puts its fingers into its mouth, sucks them or its tongue; the saliva is secreted in abundance, 'or it drivels.' On putting a finger in the mouth it presses it with avidity; if the breast is shown to it, it expresses joy, it seizes the nipple, and presses it with its hands. When on the contrary, it is not hungry, it takes the nipple with indifference, and quits it without regret, after having taken too little milk to appease hunger, if this had been the cause of its cries."—*Traité de l'Education corporelle des Enfants en bas âge.*

This is an excellent description, but it is well known that an infant often cries from many causes besides hunger; and it would be absurd to apply it to the breast whenever it cries, though women generally do so to tranquillise it. Some writers are of opinion that the infant ought to be applied to both breasts every two hours, night and day, which is about the period it generally awakes from sleep; and others recommend the application every four or five hours. According to my own observation, I think the infant should be suckled every two hours for the first month or two, during the day and night, provided it receives no other food, and that the health and strength of the mother remain unimpaired. It matters little how often the infant takes the breast—and its want of it will depend upon the strength of its constitution, the abundance and quality of the milk, and its habits—provided it thrives and is free from indigestion, and that the health of the parent does not suffer. This is the only rational and scientific precept for our guidance. When the infant is fed with other food, it will not require the breast every two hours, but all aliment except breast milk is unfit for it during the first three months of its existence. It is impossible to determine how often an infant should be applied to the breast, but after the first few weeks the longer the interval between each suckling, the better the milk, the more repose and strength for the mother. It is an error to give but one breast at each repast, the infant should be successively applied to both.

The obstetrician is usually asked two questions before his departure from the lying-in chamber; is it necessary to give the infant any

thing before the infant is put to the breast, and what interval ought to be left between its birth and its application to the breast or the first time? When the parent or the nurse forgets to ask these questions, it is the duty of the medical practitioner to inform them. It is necessary to give the infant some sugar and water, for the purpose of removing the mucosity that lines its fauces or throat. Nurses usually exhibit butter and sugar, treacle, or gruel as soon as the infant is dressed.

The breast ought to be presented to the infant when the mother has recovered from the fatigues of delivery, and the period will be longer or shorter according as the labour was quick or tedious; it is said about two hours after birth; but even sooner, when the milk is formed, the parent strong, and the signs of hunger, already described, very apparent. I cannot agree with those authors, who think that the infant should not be suckled for twelve or twenty-four hours after birth. Food of some kind should be frequently exhibited to it during either period; and the mother would be exposed to milk fever, and painful tension of the breasts. The milk of the mother, or of a woman of her own age who is delivered at the same time, is alone fit for the infant. Some authors believe that there exists between the milk of every mother and her infant an analogy which establishes a preference in favour of the maternal fluid to that of a woman delivered at the same period. The infant inherits the constitution of its mother; and she supplies the best and most natural nourishment for its preservation. Brouzet and Gardien deny that this analogy is proved; and maintain that another woman may afford as good milk as the parent. I cannot assent to this doctrine, because it is contrary to the dictates of nature, and to the analogy afforded by the various tribes of mammiferous animals.

The infant acquires its alimentation by suction of the milk secreted in the breasts of its mother or nurse, and this action is denominated suckling, and *teter* by the French. It is important to a medical practitioner to know exactly the mechanism of this action. Suction is accomplished in the following manner. The infant advances its tongue on the inferior gum, depresses it in the centre, and embraces the inferior part of the nipple. The titillation that the tongue exerts on this part, and the heat of the mouth, excites in it a kind of erection, which straightens the lactiferous tubes, while the suction causes a flow of milk. This last is effected by the infant applying its lips to the base of the nipple, then making the alternate movements of aspiration, during which the cheeks become hollow by sinking between the jaws, and a remarkable vacuity is formed in the interior of the mouth, and the movements of deglutition, during which the cheeks are prominent. The lower jaw approaches the upper, the larynx ascends and redescends, and favours the passage of the milk from the mouth into the œsophagus. Others hold that

the cheeks and lips form a pump of which the tongue is the piston, and that as the milk flows after the infant quits the nipple, respiration affords no aid to the process of suction. When this fluid is abundant it flows on the lips, and sometimes prevents the infant from swallowing it sufficiently quick, partially escapes into the larynx or "goes with the breath," excites coughing, threatens suffocation, and obliges the infant to quit the nipple. This also occurs when the infant is hungry, and sucks with too much avidity. The infant at first does not suck continually, it often ceases, and reposes, but when it acquires more vigour it is less interrupted. It must continue for some time before it extracts a tablespoonful of milk, and some suppose that it seldom takes more than three times that quantity at a single repast.

Breast milk differs in quality and quantity according to the age, health, and aliment of the individual who supplies it. We even find it different in the same woman. It may be better in one breast than in the other. Good breast milk is sweet, inodorous, of an opaline or bluish tint, and remains in drops on a polished surface. Its abundance is not always in proportion to the size of the breast, especially in full, lusty women. The best proof of its goodness and salubrity is the appearance of the infant which is reared on it; but it does not always follow, that it will agree equally well with another infant. When it is thin, watery, or deteriorated, it disagrees with the infant, causes indigestion, griping, emaciation, and vitiated alvine evacuations, of a black, brown, green colour, or almost every colour except the light yellow, which is the natural one, and an excess of urine.

On chemical analysis, the human milk contains, independently of cheese, butter, and sugar, a proportion of phosphate of lime, prepared by nature for the ossification of the newborn infant. When this is deficient, the bones remain imperfectly ossified, the teeth appear slowly and at a late period, the head and abdomen enlarge, the spine and limbs become deformed, or, to use a popular phrase, "grow out," and the infant is affected with rickets. The same defects are induced when infants are dry-nursed, or imperfectly nursed by the lower classes, of which we have numerous examples presented to our notice every day. The lower classes are compelled to commit their infants to the care of older children, or girls, who are unable to exercise them properly or keep them clean or comfortable. If we add to this, that breast milk is withheld, except in the morning and evening, and improper food substituted for it, we can readily perceive the exciting cause of rickets and deformities among children of the labouring poor. Some women secrete milk, which is too rich, and which causes indigestion, griping, green dejections or motions, and cutaneous eruptions; others, a fluid which is serous, watery, or acid, and acts as a diuretic. Different kinds of milk are observed among animals. That of one

cow forms more butter, that of another more cheese, and that of a third an acid fluid, which will not supply either substance. This difference explains the fact, that some healthful women, who have an abundance of milk, are compelled to procure wet-nurses, as their infants emaciate, and will die if suckled with the maternal fluid.

There is a principle in milk besides the preceding qualities, a vital principle, a certain degree of vitality, which evaporates on the fluid being exposed to the air, or on being boiled. In proof of this, I may mention, that if breast milk be collected in a bottle and given to an infant, a sufficient aliment is not afforded; and that women, when excited by passion, who have suckled their infants, have often caused them to be suddenly attacked with convulsions. The milk in the breast only contains the vivifying principle. A remarkable illustration of this doctrine is given by M. Leroy. He states, that the administrators of the hospital at Aix in Provence consulted the Faculty of Medicine of Paris, in 1775, to inform them of the means of preserving foundling infants, as those under their care perished about the fourth month and a half. They desired to know the cause of this disaster, and the means of remedying it. The Faculty appointed M. Leroy, as their commissioner, to give an answer. He replied that the mortality was caused by feeding the infants from a boat or cup, and that they did not receive a principle sufficiently vivifying for their conservation; that, at the age mentioned, nature commenced her efforts for development, and that the infant could not support this critical period, unless it had taken a sufficiently vivifying principle with its aliment. He advised the infants to be nourished by she-goats. These animals were driven into the wards in which the children were ranged, each went in search of the child committed to its nourishment, raised the bed covering with its horns, and placed its udder near the mouth of its charge; and in a short time children were reared in the hospital in great numbers. But the infants to whom watered cow's milk was given almost always died; this milk had lost, by exposure to air, its vital principle, and the mortality was always great when children were nurtured with this aliment. They were affected with marasmus, worms, scrofula, &c.—*Médecine Maternelle*, par M. Leroy.

Caprine lactation has been sometimes employed in mountainous districts in these countries; and we are accustomed to recommend cows' or asses' milk, warm from the animals, for the aliment of delicate children. An immense number of infants are nourished in this way; though M. Leroy states that, in Paris, he has never seen infants reared with cows' milk alone. He accounts for this statement by observing, that these animals feed upon grass and deteriorated vegetable matters, and that they give bad milk, which is incapable of strengthening the organism of the infant. Every one knows

that, in all cities, cows' milk is far inferior to that of the country, and is rendered unfit for the food of infants by the adulterations it undergoes. This last is a great evil, and one that well deserves severe punishment, as it leads to the enfeeblement of infants and children. Neither milk nor any description of food is so fit for the human offspring, as that prepared by nature. Hence the axiom, that every woman, who enjoys good health, takes wholesome food, and lives regularly, should suckle her infant. It acquires incalculable advantages when it is nursed by a healthful, intelligent, and educated mother, who watches its sensations and wants, and by her tender caresses renders it more sensitive, affectionate, vivacious, and vigorous. In fact, there are innumerable delightful feelings, which no one but a mother can experience. The infant, brought up by its mother, is accustomed to her affection and tenderness. It is not without reason, that cheerful, handsome, young nurses are preferred; as the infant is an imitator by instinct and habit, it forms the traits of its character by those of its nurse; and therefore ugly disagreeable persons are not selected. The infant nourished by its mother acquires the moral and physical resemblance of its family, so that when it is brought up, it is induced to love and preserve the social order. The bad effects of mercenary and artificial lactation will be considered hereafter.

The milk of animals contains the odour and other qualities of the aliments, on which they are fed. This holds good as regards the human subject. The air and its electrical conditions, aliments, temperament, state of health, passions, menstruation, pregnancy, delivery, and climate, modify the milk. In southern countries, the milk is less abundant and less prolonged than in the northern nations. The milk of delicate women is less nourishing than when the muscular system is well developed, without fulness of habit or a plethoric tendency.

The diet and medicine taken by a nurse will affect the breast milk, and through it the infant. The nurse should therefore be cautious in the selection of the quantity and quality of her aliments. She should take food to satiety, but not to excess. She may take whatever she relishes, as in general it will agree with her, provided her digestion is good. I have described the proper food for nurses in a former lecture, and shall only observe on this occasion, that high-seasoned, spiced, salted, smoked, oleaginous aliments, and crude vegetables are improper. Wine and spirituous liquors are injurious; fermented liquors, such as porter, &c.; coffee, chocolate, or tea should be used in moderation. The children of those who indulge in spirituous liquors are very often destroyed by convulsions. The nurse ought not to be restless, inactive, or too sedentary; she can take moderate exercise in her house, and generally in the open air, which will promote health and a salutiferous milk. As to

sleep or repose, it should not be too long or too short: from seven to eight hours' sleep will be sufficient, and longer than this, in the majority of instances, is unnecessary and injurious. The bed should not be too hard or too soft, as either is prejudicial to health.

The milk will differ in its qualities according to its age: it is too thin when old, too thick at first, becoming bluish about the sixth week, and white and saccharine from the fifth to the sixth month.

The recurrence of menstruation is prejudicial to the milk; and other food should be given during the continuance of this function. Nuptial intercourse should be moderate during lactation and pregnancy, especially when the nurse is delicate. Many women and animals, however, give milk to the moment of delivery. Lactation ought to be suspended during acute diseases, as fevers or inflammation of any part of the body, and artificial aliment substituted such as formerly described. There is no doubt but the milk is injured by the recurrence of the menstrual secretion, uterine irritation, pregnancy, and tedious labours. Children often die when suckled too long, or when the milk is too old.

When nurses have suffered hunger or much fatigue, their milk will be deteriorated, and it will become more or less indigestible when retained too long. Confinement of the bowels, like all other diseases of the nurse, will injure the infant, while the diseases of the latter will affect the former, such as apthæ (thrush), syphilis, eruptions about the mouth. Even medicines used by friction on the skin of the mother will affect the infant. MM. Pinel and Alibert made frictions with a purgative medicine on the skin of a nurse, and though her bowels were not affected, the infant was so severely purged, that it nearly died. I cannot agree with those who are of opinion that the mother, affected with catarrh or cold, will communicate the disease to her infant (Leroy); neither can I give my assent to the conclusion, that milk will be decomposed in the breasts, when too long retained. The milk when retained will certainly differ, when first drawn, from that which will be secreted by the excitement of suction; but decomposition cannot perhaps occur when the infant is suckled regularly. As yet we have no instrument to determine the good qualities of any kind of milk, and the ablest chemists have failed to elucidate this subject.

Many women deprive themselves of the power of nursing their infants, by the unnatural custom of tight lacing, which compresses the breasts, prevents their enlargement during pregnancy, and flattens the nipple. This practice should be avoided. When the nipple is flattened or small during the last six weeks of pregnancy, it would be desirable to apply almond oil at night and a breast bottle in the morning, until it becomes sufficiently prominent. If this plan be neglected, a strong child should be applied after delivery, or a

breast bottle of some kind, or a new tobacco pipe, and when all these fail suction must be made by a grown person. The application of a young dog is seldom made in this country at present. The breast and nipple should be smeared with almond or olive oil three times daily, and this washed off with mild soap and water. Suction causes a determination of blood to the bosom, and speedily increases the flow of milk. When the breast becomes distended, the infant cannot suck, and in such cases some of the above substitutes must be tried. If these prove painful, warm fomentations of poppy heads with chamomile, and the application of almond oil, will be necessary. In some cases the nipple cracks or is excoriated, and then spermaceti ointment, with a prepared teat or artificial nipple, should be employed. The infant ought not to be applied to the other breast for a day or two, and the sore one drawn with gentleness by some of the means already described. The milk it contains is injurious to the infant, and disease in one breast will often disorder the other.

Young mothers are often awkward in applying the infant. As a general rule they should sit up, have their shoulders covered with a shawl, and support the infant on either arm; should it suck in the horizontal or lying posture so much the better. The mother must be careful of cold when she is obliged to sit up.

When an infant vomits after sucking, or taking other food, it has taken too much, or it is ill. It is highly improper to re-feed it, though this is a general rule with nurses. Let us suppose a full grown and strong man has repeated vomiting, we surely would not offer him food immediately after each fit. An infant is a man in miniature, and requires to be treated in the same manner. He is subject to the same sensibilities and derangements, though in a minor degree, and these require the same treatment. At our next meeting I shall describe the diseases which disqualify a nurse, and consider mercenary and artificial lactation.

ANATOMICAL NOTES.

DISCOVERY OF THE TRUE DISTRIBUTION OF THE OBTURATOR NERVE.

BY ALEX. THOMSON, M.B., OF ST. JOHN'S CAMB.

(Concluded from page 496.)

The Anterior Series of Branches.

They leave the common nerve at the upper margin of the adductor brevis, at an inch and a half below the spine of the pubis, immediately below the anastomoses of the deep external pudic with the obturator artery, and there divide into five fasciculi, separating from each other at very acute angles, of which the *first*, or the *anterior*, is about two-thirds of a line in diameter, and plunges through the brevi-

adductori-pectineal fascia, directly forwards into the posterior surface of the pectineus; the *second*, the largest of the other four, having one line in diameter, plunges behind the interior fascia of the adductor brevis, runs under that fascia for an inch, and then plunges into that muscle, to be lost by ramifying in it; having, however, at three-fourths of an inch below the inner edge of the pectineus muscle, sent through the anterior aponeurosis of the adductor brevis, two delicate filaments, not larger than bristles, to pass, after a descending course of half an inch, into the posterior face of the adductor longus muscle, these being the only twigs it sends through the aponeurosis; the remaining three pass along the anterior face of the anterior fascia of the adductor brevis. The inner of these three descends obliquely inwards, in immediate contact with the posterior face of the adductor longus, until each line as it arrives at the middle of the inner edge of the adductor brevis, where it comes in contact with an arterial branch, running inwards from the profundati, the gracilis, adductor, magnus and longus, and skin of the inner part of the thigh, and divides there into numerous twigs, which accompany every one of the branches of this artery from the point of contact both inwards and outwards, and capable of being traced, distributing twiglets to both the arteries and veins, in the sheaths of those vessels as far as the vessels themselves can be traced. Previously, however, to coming in contact with this artery, it gives off from its inner edge, nearly at right angles, two bristle-like twigs, half an inch from one another, and the lowest half an inch above the point of contact with the artery, to pass directly inwards into the gracilis muscle without being accompanied by vessels. The *third* branch, or the second from within outwards of those on the same plane, is not larger than a bristle, and descends downwards and inwards as far as the middle of the inner posterior edge of the adductor magnus, winds round the inner edge of that muscle, having perforated the fascia, separating that muscle from the gracilis, arrives upon the anterior face of the muscle, anteriorly to its anterior fascia and descending there, obliquely outwards and downwards, becomes united by anastomoses at about an inch from the anterior inner edge of that muscle, and an inch and a half below the point of the curve forwards, with the upper of the two twigs of that branch of the anterior crural nerve that traverses the anterior face of the femoral artery from without inwards. This branch, at about the middle of its course upon the posterior face of the adductor magnus, gives off interiorly a long slender hair-like twig, traceable for three or four inches upon and ramifying into the muscle. The *fourth* branch, or the third on the same plane, from within outwards has half a line in diameter, runs vertically downwards, increasing slightly in diameter, as far as to that point of the inner edge of the adductor longus, where the middle meets the inferior

third, lying anterior to the anterior fascia of the anterior adductoral-brevial fascia, there comes in contact, without anastomosing, with the inferior branch of that part of the anterior crural, crossing the anterior face of the femoral artery to go to the skin of the inner side of the knee, descends thence along the inner edge of the adductor longus, interiorly of the fascia separating its inner edge from the adductor magnus, until such time as it arrives at the lower extremity of that muscle, then plunges into the adductoral-vastal sheath, (which in this case extends more than half way up the thigh, being formed in part by the connexion of the adductor longus tend to that of the vastus internus, as well as of the tendon of the adductor magnus to the same), gives, at this point, a small twig to the femoral artery and vein, runs down in the sheath, internally of the internal saphenic branch of the anterior crural nerve, until it is about to quit the adductoral-vastal sheath, where it becomes confounded with that nerve by interlacement of its fibres, leaving the sheath with it; having, however, previously to its anastomosis, given another filament to a branch from the femoral artery, accompanying, at this point of its course inwards, the internal saphenic nerve, not having given off any twigs in the whole of its course to the adductor magnus muscle.

The *fifth branch*, or the outermost of the branches on the same plane, that is, the outermost of the five of the anterior series, having about a line in diameter, after a course of half an inch behind the pectorali-brevi-adductorial fascia, pierces it; and, after a descending course of an inch and a half, plunges into the posterior face of the adductor longus, and is lost in that muscle, descending into it, and ramifying nearly to its extremity. Before piercing the fascia, at the moment of crossing the inner edge of the pectineus muscle, it sends through the proper aponeurosis, from its outer edge, a twig one-third of a line in diameter, which, after a descending course of an inch, is likewise lost in the upper part of the posterior face of the adductor longus.

The facts connected with the anterior series of branches were seen and verified by M. Manec and his brother, Mr. Christopher Carter, and M. Daniel Roy, surgeons, the last of whom assisted me, with great patience, in the dissection, and by Mr. Embleton. July 22, 1833.

Posterior Series of Branches.

These, arriving at the inner edge of the adductor brevis, leave the common bundle, and plunge behind the proper fascia of the adductor magnus, directing themselves inwards and downwards, give no branches to the adductor brevis or longus, and divide into two bands, after a descending course of an inch. The *inner* descends obliquely inwards, sends twigs to all the arteries it comes in contact with, expands, divides, and after a course of about three inches arrives at the lower point of the upper fourth of the inner edge of the adductor

magnus, where it plunges into that muscle after having been much divided, the longest twig, however, being distributed to the adductor-magnal twig of that branch of the profundal artery that passes inwards to be distributed to the adductor magnus, brevis, and longus, and the gracilis muscles. The *outer* branch is about two-thirds of a line in diameter, passes downwards, outwards, and slightly backwards, behind the fascia proper of the adductor magnus and brevis, continually approaching the bone until it reaches the lower point of the inner margin of the adductor brevis, then enters into a triangular space lying between the bone and the divaricated bony extremities of the tendons of the adductor magnus and longus, running down within about a quarter of an inch of the linea aspera of the femur, until it arrives at the inferior point of the inner edge of the adductor longus muscle, when it plunges into the adductoral-vastal sheath of the femoral vessels. Up to this point it gives off two twigs only, the one from about three inches below Poupart's ligament, passing inwards and downwards, and after a descending course of three-fourths of an inch, dividing into two twiglets, the one ascending to be lost in the adductor magnus muscle, the other accompanying and distributed to an arterial branch, running inwards, from the profunda, between the adductor longus and magnus, and to its accompanying veins. The second twig comes off from the outer branch, about an inch and a half lower down, running outwards and downwards, to be lost after a descending course of an inch in the anterior face of the adductor magnus. From this downwards to the adductoral-vastal sheath no twigs whatever were traced, (perhaps from this being the first time of its being traced, and from the difficulty of separating the combined tendons of the adductor longus and magnus, in order to arrive at it, a difficulty which appears also to be the cause of its not having hitherto been followed in these parts).

Upon entering the adductoral-vastal sheath it plunges into the proper sheath of the femoral vessels, running along the inner side of and in contact with the femoral artery, giving numerous twigs both to its coats and to those of the vein, until such time as that artery leaves the tendinous sheath and arrives in the ham; there it winds round the artery, crossing obliquely its posterior surface, and arrives, after a descending course of an inch and a half, on the outer side of the artery; thence descends between the popliteal artery and vein, still within their proper sheath, and remains there within half an inch of the upper edge of the inner condyle, where it divides into two equal branches, an *outer*, which appears to be the true continuation of the nerve, and continues to descend within the vascular sheath; and an *inner*, which twists from without inwards, abruptly, over the posterior surface of the artery to gain its inner side; there it pierces the proper sheath of the vessels,

directs itself downwards, inwards, and forwards, until it arrives at the lower and outer edge of the origin of the internal head of the gastrocnemius, then plunges between the excurved tendon of the semi-membranosus and the posterior ligament of the knee-joint, glides for the distance of half an inch between the two, splitting in this space into numerous filaments, that terminate by penetrating in various directions forwards between the fibres of the posterior ligament, and then ramifying upon the synovial membrane. This branch when opposite to the upper point of the origin of the internal head of the gastrocnemius sends off backwards, inwards, and downwards, a tolerably large twig, which, after a descending course of about an inch, passes into and is lost in the outer edge of the interior face of the internal head of the gastrocnemius. First of all, this popliteal branch, after quitting the adductori-vastal sheath, gives off innumerable filaments to the coats of the popliteal artery and vein, and a distinct branch to every one of the branches of the popliteal artery and their accompanying veins, passing within the common sheath of these vessels, as far down as the middle horizontal line of the posterior part of the knee-joint, where the popliteal part of the nerve divides into two branches, at the point where the descending branch arrives at the inner edge of the popliteal artery, where, indeed, the inner branch abruptly turns over the popliteal artery; the descending branch—the apparent continuation of the trunk—turns back over the posterior face of the artery at right angles, passing between it and the vein, and, when between them, divides into three branches nearly of equal magnitude—an upper, middle, and descending,—the last appearing to be the true continuation of the trunk. The upper ascends between the popliteal artery and vein for about three-fourths of an inch, until it reaches the coming off (high in this case) of the superior of the two external articular arteries, and then curves outwards before the femoral vein, to accompany and distributed to the coats of this articular artery and of its accompanying veins. The middle or largest of the branches passes from the point of division horizontally backwards and outwards, remaining in contact with the posterior face of the femoral vein, as far as its outer edge here leaving it and piercing the sheath of the vessels, curves so as to form an arch with its convexity downwards and then being directed obliquely outwards and backwards, meets and anastomoses with the upper twig of that branch of the internal popliteal nerve called the articular, at about three lines from the origin of that twig, becomes involved with it in a common sheath, passes with it to its origin, taking a tortuous course, and capable of being traced beyond that point of origin from its greater whiteness, for two inches up the anterior face of the internal popliteal nerve, when it is lost in the substance of the same nerve. The lowest of the three branches, or

the apparent continuation of the trunk descends between the popliteal artery and vein as far as to the division of the former giving numerous twigs to the coats of both, and a distinct twig to every one of the branches of the popliteal artery below the posterior horizontal median line of the knee-joint; at a level with the lower exterior superior articular artery sends a twig outwards and backwards, which forms a second arch, convex downwards with the second branch of the internal popliteal articular nerves, the arch giving off from its convex and posterior surfaces numerous twiglets, which penetrate between the fibres of the excurved tendon of the semi-membranosus, running for some distance between it and the posterior ligaments of the knee-joint, and splitting into numerous filaments, traversing the latter ligament, and ramifying in the articular fat and synovial membrane. The descending branch has also a connexion with the third branch of the articular branch of the internal popliteal nerve, and which is formed as follows:—

The third branch of the articular nerves, so called, of the internal popliteal, when, in its descending course outwards and forwards, it arrives opposite to the middle of the posterior face of the external condyle of the femur, divides into two twigs, an anastomosing and a continuing twig, the anastomotic twig larger than the other, forming, as it enters into the true sheath of the popliteal artery and vein, a third arch, convex downwards, with a twig equal nearly in magnitude to itself, curving outwards, and piercing the sheath of the vessels from the great internal branch of the popliteal part of the obturator nerve, as it is about to enter behind the recurved tendon of the semi-membranosus muscle. The arch, thus formed within the sheath of and between the popliteal artery and vein, anastomoses in this very spot by numerous twigs with the descending or continuing branch of the popliteal obturator nerve, and sends off numerous twiglets to the coats of the popliteal artery and vein, and to plunge into the spaces between the fibres of the recurved tendon of the semi-membranosus, divide there, and then slip through the holes in the posterior ligament of the knee-joint, to be distributed upon the synovial membrane. *The continuing branch* of this popliteal articular branch of the internal popliteal passes on obliquely forwards, downwards, and inwards, to accompany the internal inferior articular artery in its course, and be distributed to its coats and those of its veins.

The whole of these facts connected with the posterior series were seen and admitted by the two Manecs, M. Daniel Roy, surgeon, who aided me in the dissection, Mr. Christopher Carter, surgeon, and Messrs. Embleton and Harris.

This series of nerves was again traced out for me on the fifteenth subject with great care, by Mr. Embleton, when not only were the

same twigs and branches found, but it was also remarked, that it sent outwards twigs to plunge into the sheath of the perforating arteries as it passed them, to the profunda artery, to its perforating extremity, and to be distributed upon the coats of these and of the veins. It also sends a very large twig, that is as large as a good sized bristle, to accompany the nutrient artery of the femur, as it comes off from the profunda. This second dissection was again seen and examined by the two Messrs. Manec, M. Daniel Roy, surgeon, and Mr. Christopher Carter, surgeon. July 24th, 1833.

Obturator Nerve, traced to its cutaneous connexions with the internal saphenic nerve.

Anterior series. 15th Subject. Male, left side.—Dissected for me by Mr. Embleton. At the moment of arriving opposite to the line of junction of the pectineus and adductor brevis, a branch, about three-fourths of a line in diameter, comes off from their outer edge, perforates the brevi-longal adductor aponeurosis, runs directly downwards, between this aponeurosis and the long adductor muscle, to the upper point of the lower half of the inner edge of the latter, there comes in contact with the aponeurosis separating the adductor longus from the gracilis, runs downwards, forwards, and slightly inwards, along the inner edge of the adductor longus and interior of the aponeurosis, when, after a descending course of three inches, it arrives at the anterior edge of the gracilis, passes between this and the upper edge of the sartorius, pierces the fascia between the gracilis and sartorius, and runs again vertically downwards behind the gracilis portion of the fascia lata, as far as to level with the upper edge of the patella, there pierces the aponeurosis separating the gracilis and sartorius, and runs down in contact with the posterior edge of the sartorius behind the fascia of the leg, to terminate by anastomosing with a very large branch of the internal saphenic nerve on a level with the upper edge of the triangular patellari-ligamentum tubercle of the tibia.

Its internal edge gives off, close to its origin, a slender twig not larger than a very small bristle, which, after a descending course inwards of about an inch, plunges into the sheath of a branch of the internal circumflex artery, passing horizontally inwards, between the adductor longus and brevis; from this down to its point of contact with the Sartorius, gave off numerous small twigs varying from the size of a human hair to that of an ordinary pig's bristle, to pass downwards, and slightly inwards and forwards between the gracilis and adductor longus, to perforate the fascia lata and be lost upon the femoral portion of the internal saphenous vein and its branches, one or two of the superior of these twigs stopping short in their course to plunge into the substance of the gracilis; from thence to its ter-

mination giving off numerous slender twigs to perforate the fascia lata, and accompany in some instances the cutaneous arteries, and terminate by sub-division in the skin of the lower half of the inner face of the thigh, and the inner face of the knee. It gives off from its outer edge at the point where it crosses the lower edge of the adductor brevis, a branch equal to half its own magnitude, which accompanies an artery from the branch of the inner circumflex artery already mentioned, passes inwards, forwards, and downwards, in contact with the posterior face of the adductor longus, arrives at its inner edge at the upper point of the lower quarter of that edge, winds round it to come on to the anterior face of the muscle, then after a descending course outwards of about three-quarters of an inch, pierces the sheath of the femoral vessels, divides into two twigs, of which the upper passes directly on to the coats of the femoral artery, and the other descends for half an inch on these coats to anastomose with the twigs of the anterior crural nerve distributed to that artery. In that part of its course on the anterior face of the long adductor muscle, it sends off three or four fine twigs to plunge into the muscle, and four and five stronger than these perforating the fascia lata to anastomose with that part of the anterior crural crossing the anterior face of the femoral artery, to go to the skin of the inner part of the knee-joint.

These facts were examined and verified by M. Manec and M. Daniel Roy, surgeon. July 25, 1833.

In a subject lately dissected with M. Linton, surgeon, in which all the arteries of the legs were ossified, we traced the popliteal branch downwards, dividing with that artery, and sending a long twig to each of its branches, the posterior tibial and the fibular artery, accompanying them downwards, and sending twigs to be distributed to all their branches, and within the sheaths of the same as far downwards as to where the middle meets the inferior third of the leg.

To conclude—it results from these observations, which have been several times repeated since the writing of the above notes, that the obturator nerve is a muscular, arterial, cutaneous, and articular nerve. That it gives branches to the

1st. Adductor brevis, adductor magnus, adductor longus, pectineus, and gracilis muscles.

2nd. To the synovial membranes of the hip and knee-joint.

3rd. To the bursa mucosa of the iliacus internus, and psoas magnus, on the ilio-pectineal eminence.

4th. To anastomose with that branch of the anterior crural nerve, that crosses the face of the femoral artery near the inguinal region, to become a cutaneous nerve of the thigh.

5th. To anastomose with the internal saphenic nerve near the inner part of the knee-joint.

6th. To all the branches of the profunda, of the popliteal, posterior tibial, and fibular arteries and veins.

Thus this nerve is a compound nerve, and not simply a nerve of motion. It would appear to perform to the vessels the function of the sympathetic nerve, and perhaps may do the same to the skin. But still more probably it is in part a nerve of sensation, and furnishes the well known sympathies between the knee and hip-joint, and between these joints and the skin.

I have only to add that the branch descending into the popliteal space has this very day, Oct. 25th, 1833, been traced by Mr. Foot, and seen by Mr. Rush, by Dr. Rogers, by Mr. Charles Linton, surgeon, by Dr. Armstrong, and by Dr. Caillard, lecturer on surgery at La Pitie.

CASES OF DROPSY SUCCESSFULLY TREATED BY THE HYDRIODATE OF POTASS AFTER THE USUAL REMEDIES HAD FAILED, AND AFTER TAPPING WAS PERFORMED.

BY WILLIAM HUGHES, ESQ., M.R.C.S.

It is the duty of every medical man who may have been successful in the treatment of any difficult or dangerous cases, to communicate to the profession, for the benefit of society, the remedies he has employed, especially should they differ from the means usually resorted to in similar cases. I have always considered the publication of cases, if reported, as they ought to be, with the strictest fidelity, the most valuable portion of medical periodicals; with these feelings, I send for insertion in the London Medical and Surgical Journal, the following case of ascites, successfully treated with the hydriodate of potass. By desire of my patient, I give his name and residence, Mr. T. Shipley, 3, Newman's Row, Lincoln's Inn Fields, ætat. 36, rather stout, and of bilious temperament, never had any serious illness; had consulted me occasionally for bilious attacks, the consequence of living too freely, but which were generally removed in a day or two. In the beginning of June last, he consulted me for what he called a "fulness of the stomach," which he believed to be flatulence; upon examining the abdomen I was

convinced of the presence of fluid, and told him that it was a decided case of dropsy, and that he must have been gradually increasing in size for some time; that he must make up his mind to change his mode of living, and undergo a course of medicine. He had been accustomed to take spirits, and although, perhaps, not drinking sufficient at one time to intoxicate, taking it so frequently as to be almost constantly under its influence; at this time his general health was not materially disturbed, the alvine dejections were unhealthy and offensive; he passed but a small quantity of high coloured urine, which deposited a red sediment, but was not coagulable by heat. I prescribed four grains of blue pill every night, and diuretic medicine during the day, with an occasional purgative, composed of the compound jalap powder and the sixth of a grain of elaterium, which always operated powerfully. On the 19th I met Dr. Addison in consultation, and he, believing with me that the ascites depended on a diseased state of the liver, ordered the mercurial to be continued in small doses three times a day, in conjunction with diuretics. Without occupying your pages with a minute detail of the different medicines prescribed, and their daily effects it may suffice to state, that the remedies, usually known to be beneficial in such cases, were tried and persevered in without advantage to our patient. By the end of July the abdomen was so much distended, accompanied with some oedema of the legs and thighs, that it was thought advisable to remove the fluid, and with the advice of Dr. Addison, on the 31st of July, I performed the operation and took away fourteen quarts of transparent serum, the colour of healthy urine. I kept him in bed a week, at which time he felt himself well enough to go out, and went for change of air to Greenwich, and as his general health improved, the water again accumulated, and in six weeks the abdomen was nearly as large as before. About this time he accident-

ally met with a Mr. Cook who stated to him that he had been similarly afflicted, and that he had been under the care of Dr. Blake of Nottingham, and was cured by the hydriodate of potass. At the request of my patient Mr. Cook called on me, and gave me such a sensible and clear statement of the facts of his own case, that I was induced to write to Dr. Blake, stating my patient's case, and requesting to know how far Cook's corresponded with it, and whether he attributed the cure to the hydriodate of potass. Dr. Blake wrote me by return of post a very handsome satisfactory letter in reply. As the facts of the case are highly interesting, I shall transcribe them from the Doctor's letter. "Mr. Cook's complaint was general dropsy, arising, in my opinion, from a chronic affection of the liver, contracted during his residence in the East Indies. I first saw him on January last, a day or two after his arrival from London, from whence he was sent by his medical advisers, as being, as he, Mr. Cook, stated to me, in a decline, having then much cough and muco-purulent expectoration, with œdema of the legs, and almost total absence of bile in the evacuations, and making a very small quantity of high coloured urine, while the conjunctiva and surface of the body were slightly tinged yellow. Under these circumstances, mercury, diuretics, hydrocyanic acid, blisters, &c. were tried, but without affording relief up to the 2nd of February; at that period the cough had diminished, but the general dropsical symptoms had increased to such a degree as to prevent him leaving his bed; the abdomen was exceedingly large, the scrotum, legs, thighs, and arms, and integuments of the chest and back were likewise very much swollen, so much so as to preclude the possibility of his bending the elbow to put his hand to his head. He then commenced taking the hydriodate of potass, in ten grain doses, three times a day in a glass of water, gradually increasing the quantity to fifteen grains, which he continued to the

10th of March, with very marked benefit. The appetite and strength increased, and he was soon able to leave his bed and walk down stairs, owing to the decrease of the general swelling, which was accompanied by a proportionate increase in the quantity of urine. He omitted the hydriodate from the 10th to the 18th of March, in consequence of the intensely bitter taste he experienced, but the moment he did so the strength and appetite decreased, while the other symptoms became worse. He then recommenced the medicine with equal good effects, and continued it up to the 30th of April, when he again omitted it, thinking himself so nearly well, and on account of the disagreeable taste it left in the mouth. He however again found it necessary to resume its use on the 18th of May, and continued it to the 1st of June, with progressive improvement in every respect. During this treatment I certainly joined the administration of other diuretics and purgative medicines, but previous to the exhibition of the hydriodate, the symptoms increased rapidly, although all other medicines were most liberally given, and whenever it was omitted the disease again gained ground, so that I cannot help attributing the improvement to its tonic and diuretic effects." Dr. Blake also mentioned a case of ovarian dropsy cured by the same medicine, and also the case of a military officer, who was reduced to a skeleton from hepatic disease; the liver being so large as to be easily felt through the waistcoat, with a strong tendency to dropsy. This gentleman has continued the medicine for twelve months, and is now in good health. Upon the receipt of this letter I determined to try the hydriodate of potass uncombined in Mr. Shiply's case, giving only an occasional purgative when the symptoms demanded; the abdomen was now larger, by measurement, than when he was tapped, consequently must have contained more than fourteen quarts of fluid. He commenced on the 17th of September, with eight

grains of the hydriodate of potass, three times a day, gradually increasing it to fifteen grains. After a few doses its effects were manifested by an increase in the secretion of urine, voiding, on an average, from five to six pints in the twenty-four hours, from the 18th of September to the 24th of October. This increase in the quantity of urine was accompanied with a corresponding decrease in the size of the abdomen, and the œdema of the legs and thighs, which was considerable when he commenced the medicine, entirely disappeared. From the 20th of October, he took it only twice a day, and the 27th discontinued it; the abdomen being reduced to its natural size, and no dropsical symptoms remaining. He now complained only of weakness and profuse perspirations, for which I ordered the sulphate of quinine and sulphuric acid. His appetite is good, and he feels himself gaining strength. That the hydriodate has had a specific effect on the liver in this case, as well as the two cases mentioned by Dr. Blake, cannot, I think be denied, and I hope soon to hear of many similar cases being cured by the same medicine.

90, High Holborn.

NOTE ON THE PATHOLOGY AND
TREATMENT OF CHOLERA.

(From a Correspondent.)

THE pathological condition of the system, believed to exist in the collapse of cholera, is too well known to require detail; let us therefore inquire, what effect ought to be expected to follow a succession of powerful, rapid, and full inspirations, acting spasmodically, followed by equally powerful, rapid, and full expirations. We will imagine the immediate effects to be almost mechanical, hoping little from the operation of the vital principle.

In the first instance:—*full expansion*

of the cavity of the thorax; filling of the pulmonary artery; evacuation of the right side of the heart and venæ cavæ. In the second instance:—forcible collapse of the lungs; evacuation of the pulmonary veins; compression of the abdominal veins, and accelerated movement of their blood; compression and evacuation of the biliary ducts and gall-bladder. The several results of the whole, it is presumed, may be—free aëration of the blood; stimulation of the left side of the heart; removal of the circulation; restoration of the secretions; and evolution of animal heat.

The question then is, what will produce this forcible pumping of the vessels,—this urging on of the circulation,—this violent transference of the stagnant venous blood of the right heart through the vitalising channels of the lungs, to recal the torpid arterial system to action? To which it is replied, that, provided the Schneiderian membrane be not insensible to the stimulus of powerful errhines, sternutation may originate the chain of actions traced out above; and if the sequences are correctly anticipated, the results are not inconsistent with sound physiology.

All that is hoped for, let it be understood, from the action of errhines, is the partial recovery of the patient from that appalling condition of the system, in which nature makes “an awful pause, prophetic of her end,” and by restoring the functions, to regain our influence over them.

It is scarcely necessary to mention that hellebore, powdered gamboge, turpeth mineral, common snuff, or any other sternutatory that *would* act, will serve the end in view.

The subject of the present hint did not occur to the writer until he ceased to have the opportunity of submitting it to experiment. He now earnestly requests those who have it in their power that they will do so, and report the result. Its use is free from objections that but too justly apply to many of the remedies that have been administered in cholera; and the fact

may obtain for it a fair proof of its effects, that if it fail to realise the good expected from it, no harm can possibly attend the experiment.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, November 18, 1833.

WILLIAM KINGDON, Esq., President,
in the Chair.

Medical Reform—Bad effects of excessive Venesection in Apoplexy.

THE question of the present state of the medical profession, and of the propriety of petitioning Parliament on the subject, was referred to the Council of the Society.

Dr. Uwins observed, that, in his opinion, bleeding was very often carried too far in apoplexy, especially when occurring in a gouty habit, and accompanied by paralysis. He considered it of great importance to distinguish accurately the pathology of apoplexy, as there were some forms of the disease in which blood-letting was not only improper but highly dangerous. He referred to the disease in old persons, in whom the signs of plethora were absent. He detailed an interesting case in illustration of this opinion, and made many valuable remarks on the distinctions of M. Serres, Dr. Heberden, and others.

Mr. Dendy felt much obliged to Dr. Uwins for introducing this important subject, and was glad that a physician of such great experience had brought it before the Society. He wished Dr. Uwins to favour the meeting with the signs of sanguineous and serous apoplexy. Mr. Dendy then gave his own views on the disease, which were graphically correct.

Dr. Whiting related two cases in which blood-letting had produced syncope and coma,—in fact, apoplexy itself. He said, that the diagnosis between the forms of the disease already mentioned was formed with great difficulty.

Mr. Headland supported the pathology given by Dr. Uwins, and thought that venesection was the sheet-anchor in some cases, but unjustifiable in others.

Dr. Williams related some cases in which free depletion was the salvation of the patients. He wished young practitioners to understand, that though bleeding might be carried to excess and used injuriously, nevertheless it was the only remedy in some cases.

The President observed, that the subject of blood-letting in apoplexy and other diseases was one of the greatest importance, and he hoped it would occupy the Society at their next meeting.

Adjourned.

THE

London Medical & Surgical Journal

Saturday, November 23, 1833.

THE DEVIL UPON TWO STICKS REVIVED—MEDICAL REFORM—PARLIAMENTARY INQUIRY—PROPOSED ACTS, PERMANENT OR TEMPORARY—THE MASK OFF.

"THE COLLEGE.

"DEVIL (*as HELLEBORE, the President*), CAMPHIRE, CALOMEL, *Secretary*, and *Pupils discovered*.

SEC. "The Licentiates, Sir, will soon be at hand."

The Devil upon Two Sticks.—Act III.

In the year 1768, the genius of Foote immortalised the squabbles of the medical practitioners of that day in the celebrated comedy from which we have taken our motto. At that date the public were more disposed to laugh at the humbug of the College with its "contemptible combination of dunces, nurses, and apothecaries," and the impudence of the Johnny Macphersons,—to treat, in fact, the whole contention as a dispute for prescriptive honours,—than to look upon the question

at issue, as, in truth, involving the integrity and qualifications of that body, to whose care the public health is intrusted. If, according to the maxim, *ridiculum acri*, genuine satire could of itself work the reform of profitable abuses, we should not, in the year 1833, be witnessing a dull version of *Dr. Lest's* admission at Pall-Mall, or be bored with Presidents' lectures not very far removed from the accomplished Hellebore's dissertation upon piscatory entities. We know not whether the meetings of the College in the seventeenth century were honoured with the presence of dukes or bishops; but of this we are certain, that not even the Duke of Wellington, the Bishop of London, and the Lord Chancellor (we mean the official character, not the man), can in this age shed a lustre upon the meetings of a body, which has long ceased to be vitalised by the spirit of the medical profession.

Nor is it to this body alone that we must confine our strictures. From mere traders, a scion of "The Worshipful Company of Grocers," appropriating to itself a title which originally meant nothing more than "shopkeepers,"—the Apothecaries have gradually risen to a state of influence and power under the sanction of Parliament, which has, in fact, neutralised all the good that was contained in the charter of the College of Physicians, or might have been, under better management, elicited from it; but has not, in the slightest degree, operated to protect the public effectually against the monstrous iniquities of quacks. Things are in that state, that, if we may be allowed to suppose a continuance of the system, a physician will soon be a curiosity, a licentiate will discard the title, and this nether world will be divided between quacks, chemists, and apothecaries. But these things cannot be. The time is ripe

for medical reform. The word has escaped our lips,

"Fugit irrevocabile verbum."

It is now the bounden duty of all honest men to put their heads together, and to devise means—for the promotion of medical knowledge—for the downfall of imposture—for the knitting together *all* ranks of the profession into one organised body. Here is a question whose importance to the general welfare cannot be too often impressed upon the public. Every father of a family is interested in it. The state of such a large profession, in this vast kingdom, deeply affects every young man, who has to choose his way of life. To the statesman it assumes a still grander aspect, as he extends his view to the whole topic of medical police—a topic which has yet to find its legislator among us. Whosoever shall frame

"A hoop of gold, to bind our brethren in,"

Shaks. Henry IV.

will have done his country a service, whose blessings will "spread undivided, operate unspent,"—a sufficient reward to a great mind.

Even fools are intermeddling. With the impotence of a death-bed repentance, without a hope of life to warm their idle promise of amendment, the College of Physicians, it seems, "has appointed a committee to revise the by-laws, especially those which relate to admission into the fellowship!" We cannot pledge ourselves for the truth of this extravagant statement. The words will be found in last week's number of the *Chlorosis*. That publication is known to be the organ of the College. Perhaps, therefore, there is some foundation in fact for this new vagary. But, be the statement true or be it false, a matter of perfect indifference to the profession, it is very pleasant to observe the harmless writhings of our

cotemporary, in the same number, upon the subject of medical reform. It affirms, that the Associated Licentiate, in their late visit to Lord Melbourne, "*could not extort any indication from the noble secretary,*" (we copy the italics!) that the investigation *in petto* should be carried on by a parliamentary committee." By this slender hold, the drowning corporation, catching at a straw, hopes to stem the current. Our readers are already aware of the intentions of government, as far as it was prudent to disclose them, from the plain and straightforward dealing of Mr. Secretary Littleton with a deputation of the Irish apothecaries, reported in this journal a fortnight ago:—And we now repeat, with confidence, that nothing short of a parliamentary inquiry will satisfy the cravings of the public and the profession—that nothing short of the authority of parliament can grapple with the difficulties of the case—and that the government neither desires, nor will attempt to substitute a royal commission, independent of parliament, for a parliamentary committee.

Whether the government will itself undertake the burden of proposing the necessary bills, (charters are out of the question,) or whether it will leave the subject open for Mr. Warburton, or some other Hon. Member, may be doubtful. The latter course is more consonant with the practice of government in this country, and appears to us the more probable alternative. Could we doubt, for a moment, which of the two modes of inquiry was the more searching, the very abhorrence of the College at the thought of the House of Commons would determine our choice. Why this extreme anxiety? Does it desire the secrecy of the confessional in its dying moments, or does it grasp at some advantage in its future state, from the lenity of its self-chosen judges,

which may, in the long run, revive its darling monopoly? The profession has an interest in an open investigation of the vices of the *system* (we war not with men); and the College may depend upon it, no effort shall be spared to prevent any reserve of privilege, which can hereafter sow discord in the profession.

There is so much difficulty in foreseeing all the consequences of any arrangement which must depend, a good deal, upon the good faith of those who are to carry it into effect; there is so much difficulty in determining *a priori* the tendency of consequences actually foreseen, that it deserves serious consideration, whether it would not be prudent, in respect of our own shortsightedness, to give a temporary character to the acts which may be passed for the regulation of the profession. This is the policy on which those great national interests, the Bank and East India company, are conducted. If temporary bills, subject to revision in twenty or thirty years, were passed, there would be ample time, during that period, for experimenting upon the new system. Its operation would be seen, any unhealthy effervescence might be checked, and the *caput mortuum* removed. On the contrary, in a permanent system, it is only when the evil has grown intolerable, that there is a possibility of correcting it; such a tendency has every abuse to create a body interested in its support. This topic will, no doubt, be discussed at the approaching meeting of the Westminster Medical Society.

Our cotemporary, already noticed, after a deal of coquetting, with the virtue of a prude who has rejected overtures to her chastity, has infinitely amused us with the *pro's* and the *con's*, whether she should submit to be called "anti-radical" or "conservative." To the first title it appears, (for the mask is at last thrown

off,) she has no objection, and the public is quite right in having "more than suspected her of party feeling." The truth is too artless, too simple, for her ungoverned affections—she "occasionally strains an argument to its fullest bearing." Of this latter symptom of her love, as well as of its waywardness, she has indeed afforded many specimens. But so engrossing is her affection, that every man who is not of her clique of lovers "is broken in character and bankrupt of fortune." She demurs to "conservative," and is as delicate as Lord Byron's "*entremetteuse*.*" But after some pretty parley about abuses and all that, a compromise is struck, and with genuine unconstrained passion, she devotes herself to the interests of her lords and masters for the rest of the article.

LONDON HOSPITAL—VACANCY IN THE OFFICE OF ASSISTANT-SURGEON.

NOTHING but the last necessity shall ever induce us to bring the names of individuals in an obnoxious view before the public, where it is possible to work a public good by the assertion of a general principle. We shall leave the parties, when we can, a *locus penitentiae*. It is not a slight thing which will induce us to blast the reputation of any man, especially a young man, by a premature disclosure, whilst the guilt lies merely in intention. Those who are acquainted with the private politics of the London Hospital will fully understand the drift of these remarks, and the persons in our eye have but themselves to blame, if they force us to a duty in the last resort, from which we shall not shrink. We have had, on late occasions, to allude with severity to the too prevailing practice of nepotism in our public institutions.

* "Remember, Milor, that *delicaci ensure evert succès*."—Life of Byron, vol. vi. p. 529.

It is not easy to curb this vice,—but we have hopes the late proceedings at the London Tavern, touching this hospital, will frighten the delinquents into their propriety.

A meeting of gentlemen has been held at the London Tavern, at which Mr. Tooke, M. P., presided; where it was resolved, that the ties of consanguinity ought not to prevail in the election of medical officers to public charities, and that such influence was now being exerted for the return of a young gentleman aged twenty-three years, who received his diploma from the College of Surgeons in December last;—that merit only should have a preference;—and that Mr. Coulson, on account of his high talents and experience, was eminently qualified to fill the vacant office at the London Hospital. We sincerely trust that the above sentiments will be generally adopted by the public. *

APOTHECARIES' HALL—BOTANICAL PRIZES.

THE gold medal annually given by the Society of Apothecaries has been this year awarded to Mr. Edward Selleck Hare, student at the London University, and the silver medal to Mr. Golding Bird, student at Guy's Hospital.

Review.

Inquiry concerning the Intellectual Powers. By DR. ABERCROMBIE of Edinburgh.

ALL is not gold that glitters. Nor does this hold in trifling matters only, but in science, in literature, in every thing, in short, that should be respected. Many who enjoyed the favour of fortune, have thereby got silly

* Since this article went to type, Sir A. Carlisle has addressed the public in defence of Mr. Curliug, the gentlemen alluded to

productions puffed up. This may do for a while, but the ass's ears will at last appear.

In a letter signed Scotus, published in No. 76 of your excellent Journal, it is contended that Dr. Abercrombie's *Essay on Apoplexy*, though hitherto much praised, is altogether founded on a misconception of the anatomy of the encephalon. We have lately seen another work by the doctor, entitled "*Inquiries concerning the Intellectual Powers*," which being equal in merit, is no less eulogised. Who wrote the reviews we know not, but we have read of "a lady at court, who, having allowed an author to dedicate his works to her, resolved to see the dedication before it was printed; and not thinking it came up to her perfections, took the pains to write one of her own, and sent it to the author to place it before his works." Laudatory reviews are of little weight, when the misconceptions of the original are very glaring, and the thoughts absurd or unintelligible. That they are so in the work under consideration we do not say: let facts speak for themselves. "*Intellectual science*" says our author, p. 14, "*investigates the laws and relations of the processes of simple intellect, as perception, memory, imagination, and judgment; and the proper cultivation and regulation of these is the object of the practical art of intellectual education.*"

Some men write and others read the most extravagant nonsense, and really believe they have communicated or received instruction. *Perception is a law or a relation, and a law or a relation of a process too, and that a process of simple intellect.* We never heard of compound intellect, and we have here evinced a simplicity of intellect we never even imagined.

Again, "*Our first knowledge*," contends the king's physician, p. 43, "*is evidently of a complex nature. It seems to arise from the combined action of several senses, conveying to us the general notion of certain es-*

sences which are solid and extended, or possessed of those properties which characterise material things."

Solidity of an essence!!!

The absurdity contained in works on mind is not new. A celebrated French writer had some doubts on a metaphysical point, and he says, "A book was brought to me, called, 'The Medicine of the Mind,' by Dr. Camus, professor of medicine in the University of Paris. I was in hopes of finding in this book a solution of all my difficulties. But what was it that I found, in fact? Just nothing at all. Ah! master Camus, you have not displayed much mind in preparing your medicine of the mind. This person strongly recommends the blood of an ass, drawn from behind the ear, as a specific against madness. 'The virtue of the blood of an ass' he says, 're-establishes the soul in its functions.' He maintains also, that madmen are cured by giving them the itch. He asserts likewise, that in order to gain or strengthen a memory, the meat of capons, leverets, and larks, is of eminent service, and that onions and butter ought to be avoided above all things. This was printed in 1769, with the king's approbation and privilege; and there really were people who consigned their health to the keeping of master Camus, professor of medicine! Why was he not made first physician to the king?"

The previous specimens given of Dr. Abercrombie's intellectual powers remind me of what Baron de Valcé, in the play, says of a traveller: "His genius rises so far above mine, that I comprehend his long harangues no more than if they were spoken in Hebrew. His language abounds with a number of words, to me absolutely unknown: while he places those I do understand in such a way, that I am quite at a loss to find out their meaning." Now it is evident that we must use our words correctly, if we wish to be understood; and our author has some vague idea of this, for he says, p. 346, "Much of the fallacy and ambiguity of processes of

reasoning, depends entirely, as formerly stated, *on the use of terms*." Here is meant *abuse of words*, and therefore it will be readily granted, that this style of writing should be called the economical: for by it an author happily manages to commit the very error he is condemning.

The doctor, for the avoiding of such faults, recommends the defining of our words. He himself follows this rule, and his success therein may be estimated by the following specimens. "THE IMPRESSIONS" says he, p. 40, *derived from external things* are to be considered as the OCCASIONS *on which the various powers of the mind are brought into action.*" And at p. 97, "By memory *we retain the impression of facts or events*, and by recollection *we recall them* into the mind by a voluntary effort." So an *impression* is an occasion on which powers act! and it is the retaining of this occasion of a fact that constitutes memory! Could the learned doctor himself point out any meaning in the above jumble of words? Nor is this all. Even supposing the definition of *impression* to be correct, that of memory and of recollection is absurd. The whole presents a most extraordinary abuse of language. When we come in contact with a body, there is an impression; but can *we retain this impression*? And if we could, would its retention be memory? We may recall the idea of an event, but to *recall the event itself into the mind* is something original. It would indeed be highly interesting to see the mind of a member of a Board of Health, with all the peculiar facts and events in it. If this is the basis, what must the superstructure be.

Again; "*Conception*," we learn at pages 97 and 125, "*is the recalling of a perception*," and though the recalling of a perception, yet (p. 126) "*it does not appear to be necessarily connected with the impression of past time.*" Wonderful! To recal a thing not past! Probably this was intended for something very fine—something figurative—a new kind of antithesis,

for instance. Be this as it may, though we may recal an idea, to recal a perception is impossible. If, however, to please the Doctor we could contend with impossibilities, aye, and overcome them, we would be no less puzzled. For when we say of a poet, his conceptions are fine, we refer not to ideas recalled, but to the result of his creative fancy. We could furnish many more equally instructive *definitions*, but our space prevents us, and, in truth, it would be unnecessary, as it would be almost impossible to give more striking examples of the purely unintelligible.

Since many can draw conclusions correctly who never studied logic, so the King's physician may be profound and just in his reasonings, even though he knows nothing of reason (*viz.* his definition of it, p. 170). And to facilitate the decision of this question, we shall present our author's ideas on "First Truths," or "Fundamental Principles." These we are told are INTUITIVE, (pages 69, 187, 208, 215, 232); and, introducing a manifest contradiction, that they are INSTINCTIVE (pages 69, 213). We learn, also, that they neither result from, (p. 187) nor admit of, proof by processes of reasoning (pages 71, 209, 244), while they are known by intuitive reasoning (p. 224), or by a certain exercise of the understanding (p. 69), or are themselves a spontaneous and instinctive exercise of reason (p. 41); and, though they neither require nor admit of proof (pp. 187, 208), yet they are proved by an appeal to every man's absolute conviction (pp. 189, 209, 224).

As the reader may be desirous to know what is meant by principles which are intuitive, instinctive, not known by reason, known by reason, not capable of proof, and proved; and as the desire is very commendable, we shall furnish an example or two.

Causation is a fundamental principle, *intuitive* (p. 190), *instinctive* (p. 9), and *logically adduced from certain data* (pp. 6, 217.)

Our confidence in the uniformity

of nature, also a First Truth (p. 190), is an *instinctive conviction* (p. 191), and this conviction is an instinctive principle (p. 192), and though an instinctive, *a fairly drawn conclusion from well-ascertained facts* (p. 193). Our author adds (p. 192), "Such is our confidence in the undeviating uniformity of nature, that, whatever number of these qualities we have ascertained to belong to a substance, we expect to find in every specimen of it in all time coming." And one of the examples brought in illustration, is the "uniformity of the botanical characters of plants" (p. 191), which shows, that a good metaphysician as the Doctor, no doubt, supposes himself to be, may be a bad botanist. Has he never observed any variety even in the number of the stamina? Probably not, for he tells us (p. 192), "I never calculate upon the possibility of being deceived in any of these particulars."

These mirabilia will call the public attention; and those gentlemen who so seriously recommend the work, will, no doubt, furnish a satisfactory explanation of them, greatly to the benefit of science.

CONSPIRACY AGAINST A PHYSICIAN.

WE insert the following documents, as the individual (who is unknown to us) to whom they refer, has lately been charged with criminal conversation with a patient, but the Grand Jury at Dublin ignored the bill of indictment. We feel proud to state, that the immense body of our profession has, with only three exceptions, during the last century, acted on those high moral and christian maxims, which have ever guided the honourable and useful faculty to which we have the honour to belong. They have, as their Academic oath requires, practised *cauté, casté, probéque*; and will, as Englishmen, ever continue to do so.

At a General Council, held at Apothecaries' Hall, on Wednesday, 30th

October, 1833, the following Address was unanimously voted to Charles Johnson, Esq., M.D.:—

We, the Governor and Council of the Apothecaries' Hall of Ireland, feel it our duty, as a public professional body, to offer you our congratulations on your escape from the toils of the infamous conspiracy formed against your character, and in your person, against the honour of the use and dignified profession of which we all pride ourselves on being members.

Were such an attempt to escape that condign punishment, which most effectually results from an open expression of public indignation, there would be no safety in society for the Medical Practitioner.

But favoured with a system of legislation, which searches with the all-seeing eye of Justice into the inmost recesses of the guilty breast, the dark shadow of false accusation rests but for a moment on the innocent, only that the bright light of truth may fall, with unclouded brilliancy, upon his forehead, whose heart is devoted to honour and the best interests of science and humanity.

We offer you, Sir, our heartfelt congratulations at the success with which you have repelled those base accusations, and hope that your professional career shall continue to be as honourable and successful as it always has been.

Signed by order of the General Council, Apothecaries' Hall of Ireland,
WILLIAM MADDEN, *Secretary*.

To the Governor and Council of Apothecaries' Hall of Ireland.

Gentlemen,—I cannot but feel gratified to find the Members of the different Departments of the Medical Profession coming forward to address me on the present occasion.

A base attempt has been made to injure my reputation; that attempt has totally failed, and it is most satisfactory to me to receive on this occasion public expression of confidence

and approbation, from those whose good opinion I most value.

The expression of such sentiments, coming from so respectable a public body as the Governors and Council of the Apothecaries' Hall, is particularly gratifying to me, and I beg, Gentlemen, that you will convey to them my best thanks for the Address with which they have honoured me.

I have the honour to be, Gentlemen,

Your obedient humble servant,

CHARLES JOHNSON.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Divison of the Ulnar Artery—Ligature.

A SICKLY looking man, about forty years of age, was admitted into the hospital some weeks ago, from the following accident. He had been endeavouring to raise a window, when suddenly losing his hold his hand passed with violence through the pane of glass, by which the ulnar artery was completely divided close to the wrist.

The hæmorrhage was very profuse, and he was conveyed immediately to the hospital. On examination it appeared that the ulnar artery had been divided, and a ligature was immediately passed round the artery, within a short distance of the carpus. The patient has gone on remarkably well since the operation, and is now almost recovered.

Fracture of the Patella.

A strong robust man, ætat. 35, was admitted with transverse fracture of the patella. On examination there was found to be a considerable space between the two parts of the bone, which on pressure with the hand was very perceptible. This was caused by the extensor muscles of the leg acting to draw up the superior portion of the patella. There was considerable œdema of the knee, and the patient was entirely unable to stand, on account of the extensor muscles failing to move the leg.

The treatment of this case was as follows. The thigh was bent back on the pelvis, in order that the power of the muscles might be diminished in consequence of the relaxation of their fibres. The leg was then extended in a horizontal position, gradually ascending from the tuberosity of the ischium to the foot. The leg was securely bandaged and the patient kept completely at rest.

The patella, when broken, always reunites by ligamentous and not by bony union.

MIDDLESEX HOSPITAL.

Cases of Hemiplegia.

I forward you three cases of hemiplegia, all depending upon and distinctly referred to a fit of apoplexy; in my next communication I shall send you three other cases of hemiplegia, but dependant upon other causes, and referred to no distinct apoplectic attack. When hemiplegia comes on after an apoplectic seizure it is quite uncertain what will be the result of the case. Of course we form our prognosis after maturely and carefully considering every symptom and feature. We must ascertain the nature of the fit, whether it be short or prolonged, whether severe or otherwise. The age of our patient, his habits, his appearance, and his occupation must all be taken into consideration. We must inquire into the state of his health previous to the attack, and above all things ascertain if there is disease of the heart.

In those cases of recovery from apoplexy where subsequent hemiplegia remains, this latter affection I have observed to be more under the controul of remedies than where there are no symptoms of effusion.

The following cases, as embracing several pathological facts, will I am sure be interesting to your readers.

Samuel Bedsted, ætat. 50, a waterman, stout and plethoric was brought to the Middlesex Hospital and placed under the care of Dr. Watson, Dec. 5th, having just recovered from a fit which he was suddenly seized with a quarter of an hour before admission. His face is flushed, the right angle of the mouth is drawn towards the same ear, and there is hemiplegia of the left half of the body. He complains of pain over the right half of the forehead and head. Pulse 90, full and hard. The only account which could be obtained was, that he had a severe fit of coughing upon getting up in the morning, and that he had not felt quite well since, although he was able to go about as usual.

VS. Ad. 3xxxvj. Abradat. cap. et lotio frigida applicanda.

Calomel, grs. iij. stat. et rep. 3tis.

Enema terebinthinæ.

6th. Considerable improvement; he is quite collected, and says he has no pain; bowels freely open; pulse 100, much diminished in power; a slight mercurial fœtor; sensation a little diminished, but motion quite gone in the left side.

Habeat. Hydrarg. c. Creta gr. v. 4tis.

13th. Is able to move the leg, not so the arm; passes his urine involuntary; excoriation of the sacrum.

21st. Has suffered from a slight relapse; pain in the head, which is referred to a particular spot.

Hirudines iv. part. dolent. Mag. Sulph.

3j. ex. Infus. Ros. ter die.

25th. Relief from the leeches; can move

the leg tolerably well; no improvement in the arm; face still turned to the right side. From this time he gradually improved.

Feb. 1st. He was made an out patient, and returned to visit his physician from time to time, and the report, April 1st., is, that he has nearly entirely regained the use of his limbs, and has no complaint, except that the features are a little distorted.

In September he returned with some threatenings of a fit, but this was relieved by the usual means.

Elizabeth Carter, *ætat.* 56; married, no children; admitted under Dr. Watson, March 12th; states that she was attacked three days ago with pain in the back extending up the spine; upon attempting to stand, she fell down in a fit, and was quite insensible; when she recovered she found that she had entirely lost the use of the left side of the body. There is now perfect hemiplegia of that side, with paralysis of the parts supplied by the left *portio dura*; sensation is slightly diminished.

Hydr. c. Creta, gr. v. ter.

14th. Wanders occasionally; says that she is better.

22. During the last week she has been getting worse; there is more insensibility and increased delirium; paralysis on the increase; pupils act only with a strong light; pulse hardish; picking of the bed-clothes and subsultus; was bled three days ago with relief. The temporal artery was now opened, but no benefit resulted from the abstraction of blood; coma came on, and she gradually sank, and died on the 24th.

Pathological Appearances.

Chest.—Lungs healthy; heart, flabby, large, and surrounded by fat.

There were found numerous cheesy deposits in the aorta, so thick that the yellow matter might in some places be squeezed out.

Head.—The ventricles contained a small quantity of serum. Just upon the outside of the right corpus striatum, and between it and the medullary matter, a coagulum was observed, about the size of a large walnut. Around the coagulum the cerebral substance was softened, and of a brownish-red colour.

WESTMINSTER HOSPITAL.

Removal of a fungous mass growing from the Tunica Albuginea of the Testicle.

MAUNDY, a strong athletic man, about thirty years of age, was admitted into the hospital some time since, with a fungous growth from the tunica albuginea of the testicle; he stated, that about three years he received a very violent blow on the testicle; this was soon succeeded by a very painful tumefaction of the gland, which became exceedingly hard. After the lapse of some time, the scrotum began to ulcerate, and an opening formed

through which issued a thick firm fungus. The surrounding parts became indurated, and the disease became very extensive. For some time it remained indolent, but the pain being excessive, he at length came to the hospital.

The fungus in this case was found to be completely divested of all malignancy, and Mr. White (under whose care the patient was admitted), seemed to think that the testicle itself was quite free from disease, the fungus having its origin in the tunica albuginea.

Several applications, and among others iodine, were used without effect. An operation was then proposed, to which the patient reluctantly consented.

On Saturday last the patient was brought into the operating theatre, extremely apprehensive that Mr. White intended removing the testicle itself.

Mr. W., having made two elliptical incisions, one on each side of the fungous mass, completely detached the diseased growth from the surface of the tunica albuginea. He then pared off all the remaining portions of disease from the coats and the spermatic chord. The hæmorrhage was not very great. The patient appeared to suffer intense agony during the operation. One or two small arteries were tied, and the edges of the wound approximated by sutures and adhesive plaster.

18th. Patient going on well since the operation; complains of pain in the testicle; slept well last night.

VOL. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXV., DELIVERED MARCH 8, 1833.

GENTLEMEN,—I mentioned to you that our museum is poor in specimens of exostosis: there are not more than two or three in the whole of the collection. One of them was shown to you a few evenings ago, when we were considering the effects of inflammation of the osseous texture. But the preparation which I now show you is perhaps the best we have: it is a small narrow-necked exostosis, growing from the upper part of the tibia.

Annexed to Sir Astley Cooper's valuable Essay on this subject, you will find several plates illustrative of the varieties of exostosis. The plate, which I am now examining, being on a small scale shall be passed round for your inspection; it exhibits the most frequent situation of an exostosis when the tumour occurs on the thigh-bone, namely, just below the attachment of the tendon of the long head of the triceps. In this plate, annexed to Sir Astley Cooper's Essay, you see the representation of an ingenious kind of saw, invented for the removal of exostoses which are so deeply situated that they cannot be divided with any common description of saw, on account of the injury that would be inflicted on the soft parts. The instrument, you will observe, is worked by machinery. The other figure represents a fungous exostosis, growing from the forehead; an attempt was made to remove it, but the operation was unsuccessful, and the patient died. This represents another kind of exostosis, sometimes called *cellular*, for it is of a cancellous structure, which is continuous with the medullary texture of the bone. The next shows the size of an exostosis, compared with that of the limb, in a woman who was under the care of Sir Astley Cooper.

VOL. IV.

Another figure represents the *periosteal exostosis*; while the last exhibits a *fungous exostosis from the medullary membrane*, as described by the same experienced and very practical surgeon.

Gentlemen, the next subject, to which I request your attention, comprises the *diseases of the joints*, a class of cases not only of common occurrence, but often difficult of cure, and sometimes terminating in permanent lameness, or even the death of the patient.

With regard to *inflammation of joints*, I need not detain you long upon it, because it has been already noticed, when we were considering the effects of gun-shot wounds and compound dislocations. It is chiefly in relation to inflammation of joints, produced either by external violence, or by the influence of extraneous substances within the synovial membrane, or by the action of a few other causes, that the surgical lecturer has to consider the affection. Rheumatic and gouty inflammations of the joints of course, will, be fully explained to you by the Professor of Medicine.

Amongst the exciting causes of inflammation of joints, are *wounds of those parts*, which injuries are more or less dangerous according to circumstances. One thing that makes considerable difference in this respect is the size of the joint. When this is large, like the knee, a wound in it, especially a wound that is not a clean incised one,—that has been produced with great violence and roughness—will be of a very serious nature; for gentlemen, when a wound gives rise to active inflammation of the synovial membrane of a joint of considerable size, the symptoms may be so severe as to endanger the patient's life. A wound of the knee-joint, also, though it may be a clean incised one, or a puncture made in the gentlest way, if proper care be not taken of the case, will frequently be followed by severe inflammation of the synovial membrane, and consequences involving the loss of the patient's limb, or even life. The danger of a wound, then, which penetrates the synovial membrane, depends, first, on the size of the joint; secondly, on whether or not there is much contusion or laceration in

N N

addition to the mere division of the synovial membrane; and thirdly, on the extent of the laceration or opening in the latter texture. Wounds of the knee-joint from gun-shot are sure to be followed by so dangerous a degree of inflammation of the synovial membrane and all the surrounding parts, that amputation is generally regarded, by the most experienced surgeons, as the proper measure, which should always be resorted to before the perilous circumstances to which I have alluded have had time to come on. However, I am now speaking of gun-shot injuries,—very different cases from a wound of the knee-joint inflicted with a sharp instrument, and unaccompanied by laceration or contusion. The latter case may bring on no severe inflammation of the synovial membrane; and the knowledge of this fact has encouraged many surgeons to open the knee-joint purposely, either for the discharge of fluids, or for the extraction of loose cartilaginous formations from the articulation, which, acting like extraneous bodies, occasionally give rise to a good deal of pain, lameness, and inconvenience.

The principal indication in the treatment of wounds of the joints (supposing you are not called upon to amputate by any of the circumstances I have mentioned) is to prevent inflammation from invading the synovial membrane; and one of the most important means of accomplishing this desirable object is to endeavour to bring about an union of the external wound as quickly as possible. Then, with the view of promoting the indication I am speaking of, you must keep the joint quiet and motionless. Even wounds of the simplest description, if the joint be moved, will excite severe inflammation of the synovial membrane, and all its usual effects on the system at large. If the wound and joint inflame you should have recourse to the strictest antiphlogistic treatment; it will be necessary to bleed the patient freely and repeatedly, and also to apply leeches or cupping glasses to the integuments of the part. Poulices, fomentations, and other applications, usually employed for the relief of inflammation, will be necessary. In some instances, cold applications will be more agreeable to the patient's feelings than warm ones, especially in the early stages of the inflammation, and then I think they ought always to be preferred by the surgeon. Bleeding, aperient medicines, calomel, and quietude, are among the most important measures for keeping off and lowering inflammation of the synovial membrane. The calomel is to be joined with small doses of opium, and repeated in doses of two grains every four or six hours, if the knee-joint be attacked, and the symptoms urgent. Instead of amputating in cases where the elbow-joint is severely wounded, some surgeons prefer excising the articular portions of the bones, a practice that has an advocate in Mr. Syme of Edinburgh. If this plan be followed, it must be done without delay, that is to say, when you see at the first

inspection of the accident, that there is no chance of curing the injury and preserving the joint, you should not wait for inflammation to come on, but perform the excision of the injured joint without delay. The patient will then have ten times more chance of recovery, than if you were to put off the operation. As for injuries of the shoulder-joint, accompanied by splintering of the bones, it is well known to all experienced military surgeons, that the upper extremity may frequently be saved, under these circumstances, by making an incision through the deltoid muscle, and extracting the splintered portions of the head of the humerus, and even those of the scapula, if a part of the latter bone should be implicated.

Wounds of joints are generally indicated by a discharge of the synovial fluid, which is a yellowish glairy oleaginous liquor, having very much the appearance of the white of an egg. You may also suspect what has happened by considering the direction of the wound and the weapon, and force that has been applied; for the escape of a fluid, possessing the characters of synovia, is not to be entirely depended upon; for sometimes the wound may penetrate the fibrous sheath of a tendon, and then it may be followed by the discharge of a glairy oily fluid, though the capsule of the joint itself may not have been pierced at all. The symptoms of acute inflammation of the synovial membrane of the knee, occasioned by a wound, are generally very severe; the patient has a small accelerated pulse, and there is great tendency to disturbance of the stomach, spasmodic twitches, and even delirium. I have seen wounds of the knee-joint in mechanics, produced by the instruments with which they were working, followed by incessant nausea and sickness for several hours after the occurrence of such accidents. In these cases, unless the most efficient treatment be pursued, delirium will sometimes come on with great rapidity, and then the patient will generally be lost.

When the synovial membrane is inflamed, it may become the seat of a serous effusion, or of a purulent secretion. Sometimes coagulable lymph will be thrown out on the surface, as illustrated in some of the preparations which I showed you when we were considering the subject of inflammation; and if the inflammation go on, the synovial membrane may ulcerate, and the cartilages become absorbed. Here is a specimen, in which the synovial membrane of the knee has been inflamed, in consequence of a fracture of the patella, and you will observe, that coagulable lymph is effused, and in some places the cartilages absorbed, and the synovial membrane ulcerated. Most of the other preparations on the table illustrate the same things; this is one in which lymph has been effused in consequence of inflammation of the synovial membrane, and in which ulceration of the cartilages is commencing; you see how much the synovial membrane is thickened in some

places, and the other parts ulcerated; the cartilages are likewise beginning to be absorbed, and the surface of the bone to be uncovered. But, gentlemen, I need not be more prolix on these matters, as I called your attention to them, when noticing inflammation in general, and of its effects on the different textures of the body.

As soon as the inflammation of a joint puts on a chronic form, the treatment must be changed; you must not bleed from the arm, as in the acute form of the disorder, though leeches and cupping may yet be beneficial. Now also counter-irritants may be brought up to the patient's assistance with great advantage, as the antimonial ointment, blisters, or, in a still later and more chronic stage, hydriodate of potass blended with common ointment, or with mercurial ointment, may be rubbed on the part, or camphorated liniment with iodine. The pressure of a bandage or laced knee-cap will also be useful in diminishing the thickening, which remains after the subsidence of inflammation.

Hydrops articuli is another affection of the joints, requiring your notice; it may arise in consequence of various circumstances. In this disease the synovial membrane, which is usually that of the knee, is filled with a fluid, less glairy and much thinner than the natural synovia, so that when the joint is moved, the cartilages will sometimes make a grating noise. This is owing to the altered quality of the fluid secreted into the cavity of the articulation: The effusion distends the synovial membrane much in the same manner as the fluid in hydrocele distends the tunica vaginalis. Various circumstances may bring on the disease: it occurs most frequently in rheumatic subjects, or those who are predisposed to inflammation of the synovial membrane from rheumatism. But in certain constitutions, any slight sprain, or contusion of a joint, will bring on *hydrops articuli*; and in them any exposure to damp or cold will produce the same effect. The disease may also occur after a fracture near the joint, as of the condyles of the femur, or of the patella, when these accidents are followed by inflammation of the synovial membrane. In the knee, this disorder is attended by a soft swelling accompanied by fluctuation; the knee-pan is considerably raised; it projects forwards, and can be pushed back into contact with the femur, but on removing the pressure, its displacement immediately returns.

The treatment of this disease varies according to its particular cause, the degree of inflammation attending it, the stage which it is in, and other circumstances. In the beginning, when inflammation is still present, the treatment should be antiphlogistic; you should employ general and local bleeding, and calomel in repeated doses, saline aperients, poultices and fomentations. After the inflammation has subsided, you may begin with discutient lotions, or those containing the muriate of ammonia, vinegar, and camphorated

spirit of wine in proper proportions, taking care, however, not to let them be too stimulating at first. In beginning the use of a lotion, it is frequently prudent, to apply merely an astringent one for two or three days, such as liquor plumbi acetatis dilutus, and then to commence with others of a more active kind. From these you may proceed to blisters, which will have the greatest effect in promoting the absorption of the redundant fluid. But, besides blisters, we have other powerful means of relief, as friction with iodine liniments and ointments, the antimonial ointment, and the pressure of a bandage or laced knee-cap. The occurrence of *hydrops articuli* in any other joint than the knee is rare.

Loose cartilages sometimes form in the joints, but more frequently in the knee than any other joint. They are, however, now and then met with in the articulations of the lower jaw, elbow, and ankle. But it is principally when they are situated in the knee, that they become the subjects of surgical attention. Sometimes they are quite loose; in other instances they are connected by a kind of pellicle to the capsule; sometimes there is only a single one in the joint; on other occasions, their number may amount to twenty or thirty. Frequently their central part is of an osseous consistence. Generally one side of them is convex, and the other concave; they are of an oblong figure, and occasionally not larger than a pea, but sometimes nearly equal to the patella in size. As long as they retain their attachments to the capsule of the joint, they do not usually cause much inconvenience; at all events, they cannot then occasion any irritation, or any interruption of the movements of the joint by slipping between the condyles of the femur and the tibia; but when they are loose and slip about, they are liable to become pinched between those condyles and the head of the tibia, and then the patient is suddenly seized with violent pain in the joint, and loses for a short time the use of the limb. These attacks are frequently followed by more or less inflammation of the synovial membrane, so that the patient is obliged to confine himself to his room for a few days. At length these attacks of pain and inflammation in the joint become seriously annoying, and then the patient generally consults a surgeon. With regard to the manner, in which these substances are produced, the doctrine sometimes entertained in this country is, that they arise from inflammation of the synovial membrane which pours out coagulable lymph, and which, becoming organised, is transformed into these cartilaginous substances. At first, therefore, they are supposed to be attached to the synovial membrane, and are capable of growing; but, that in time they become loosened, and then undergo no further increase of their size. As long as they are attached, they have a vascular connection to the synovial membrane, and are capable of growing; but, when they are

broken off, they do not increase. In this loose and moveable state, however, they may be exceedingly troublesome, as I have already explained. I ought to mention, that the above explanation of their origin is not adopted by all pathologists; for it will not account for the situation in which some of them are found. Cruveilhier has met with them so situated as to be covered by the synovial membrane, that is to say, the synovial membrane intervened between them and the cavity of the joint; they were in fact in the cellular membrane on the outside the capsule of the joint; and you will find in his engravings a representation of one of them on the head of the tibia, external to the capsule and, as it were, under it. Mr. Brodie in his work on the diseases of joints, also refers to a case, which fell under his notice, and could not be accounted for on the principle of the organisation of coagulable lymph effused upon the inner surface of the synovial membrane. We know likewise, that portions of the natural cartilage of the joint sometimes break off, and then loose cartilaginous substances within the capsule are produced in quite a different manner from what has been suggested.

Treatment. — Whether these substances should be taken out, or not, depends on two circumstances; first, on the degree of annoyance suffered by the patient, and secondly on his willingness to encounter an operation, when the risk of it has been fairly and correctly explained to him; for, it must not be dissembled, that some individuals who have submitted to the operation, have had severe inflammation of the joint brought on by it, and have lost their lives. They therefore sacrificed themselves to an experiment, made in the hope of freeing them from what is commonly a very endurable complaint. But, gentlemen, supposing a person were to be prevented from getting his bread by this disease, and were not only willing, but desirous to submit to the operation, after its danger had been rightly explained to him, and other measures had failed to give him relief, then, I should say, that the operation ought to be performed. I attended a gentleman about two years ago, who had a large cartilaginous substance loose in the cavity of the knee joint, which prevented him from following his affairs; he used to be attacked with inflammation of the synovial membrane every two or three weeks. I explained to him the risk attending the operation, but he chose to encounter it, and fortunately he got well without a single bad symptom coming on. The cartilaginous formation was of about half the size of the patella, with one side convex, the other concave. Last year I showed it to the class; but I believe it is now lost. It is right that the patient should always be apprized of the risk of the operation, for generally very considerable relief may be derived from the pressure of a bandage, or from wearing what is called a *laced knee-cap*. If you operate, it is a good plan not to make

the incisions through the skin and the synovial membrane exactly opposite each other. I advise you to draw the integuments to one side, and then cut through them and the capsule, and thus, when the integuments resume their natural place, the aperture in the capsule will be closed. The situation, often considered most convenient for the operation, is over the internal condyle; you may try to fix the foreign body in that place, and after you have exposed it, you are to take hold of it directly with a tenaculum, or it may slip away into another part of the cavity of the joint, whence you may not be able to remove it so as to bring it out of the wound you have made. As there is a risk of the supervention of inflammation after this operation, it is always prudent, for two or three days before you undertake it, to keep the patient in bed, or perfectly quiet in his room, to restrict him to a low diet, and to give him an aperient mixture. Above all things, be sure to make him keep the joint perfectly quiet, and covered with cold lotions; and never operate while the joint is at all hot, painful, or disposed to inflammation. If inflammation come on after the operation, trust to copious and repeated bleeding, leeches, mercury, purgatives, and cold applications. Supposing the cartilaginous substance were rather large you would not attempt to force it through an insufficient opening in the synovial membrane, for this plan would be more likely to bring on inflammation, than if you were to enlarge the wound to the desirable extent. Be sure, however, to make it no larger than actually necessary, as the danger of wounds of the knee is in a great measure proportioned to their size.

Another disease of the synovial membrane, called the *pulpy thickening of it*, is a disease generally reputed to be of a scrofulous nature. Not many years ago, many very different complaints were all confounded together under the name of *white swelling*; thus, a disease beginning with ulceration of the cartilages; a scrofulous disease, commencing in the heads of the bones; and this pulpy disease of the synovial membrane; were all jumbled together under the head of white swelling. The disease which I wish to describe occurs chiefly in young persons, in those who are under the age of twenty-one, or not much above that age; in individuals between the ages of sixteen and twenty-two or twenty-five; and is mostly met with only in the knee. At first, the pain is inconsiderable, merely amounting to a stiffness, accompanied by a slight swelling and rigidity. The disease, therefore, may be said to come on slowly and insidiously. By degrees the swelling increases, and, on touching it with your finger, you will find that it communicates a sensation as if it contained a fluid, there being considerable softness and elasticity about it. In time the joint is nearly destroyed. Yet the pain is not very severe; indeed you do not find it occasion any suffering till abscesses form in the synovial membrane, or on the outside of it. The disease will sometimes go on for several

years without rendering amputation necessary; it is one of those tedious diseases, in which the patient lingers a long time without getting well, and yet without being reduced to such a state as absolutely to be obliged to submit to amputation. At last, however, the hectic symptoms become aggravated, and amputation is unavoidable. According to Mr. Brodie, who first discriminated this case from other forms of disease classed as white swellings, it is incurable, inasmuch as it consists in a total disorganisation of the synovial membrane, which is converted into a brownish or lightish brown pulpy substance, varying from a quarter to half an inch or more in thickness. It is then an organic disease, and white lines may be seen crossing the pulpy substance in various directions. In the advanced stages of the disease, the cartilages, ligaments, and bones of the joint become diseased, or destroyed. There are, however, some surgeons, who do not coincide with Mr. Brodie, as to the total incurability of this affection, among whom I observe is Mr. Syme of Edinburgh, who contends that it is frequently cured. On the contrary, Mr. Brodie has found, that it is not only incurable, but that it admits of no kind of amendment. Generally, the whole synovial membrane is changed in the manner described; but in a few instances only a portion of it is attacked. In the majority of cases, gentlemen, you may recognise the case by the very gradual progress of the enlargement of the joint, the stiffness without pain, and the soft elastic feel of the tumour:—such are the characteristic marks of the pulpy thickening of the synovial membrane. The sensation much resembles that of fluctuation from the presence of fluid; it may be distinguished by an experienced practitioner, but a careless one might be deceived.

Treatment.—Mr. Syme, who considers the disease not totally incurable, recommends quietude of the joint, which is to be maintained by the assistance of pasteboard or other splints. This principle applies to all chronic diseases of the joints. He also puts the patient on a regimen calculated to improve his general health. If there be inflammation in the part, he attacks it by means of leeches, cupping, &c., and with a view to promote the absorption of the pulpy substance, into which the synovial membrane is converted, he recommends blistering the part, and the application of iodine preparations, or iodine with mercury, and the hydriodate of potass ointment.

Mr. Scott, of London, has a particular mode of dressing diseased joints. He surrounds the joint first with soap plaster, blended with mercurial ointment; over this he applies straps of *emplastrum plumbi*, and then common soap plaster, spread on thick leather. Now it is manifest to me, that whatever efficacy this method may possess, it is not to be ascribed to the mercury, or to the particularity with which the dressings are put on, but to their effect in keeping the joint motionless. I should say, then, that if a more simple and less trouble-

some way of keeping the joint motionless were adopted, it would be more correspondent to the plain ways of good modern surgery, than all this farrago of plasters and dressings. No doubt, the keeping of the joint motionless is one of the most important means in the treatment of the disease, and whether you adopt Mr. Scott's method, or use common splints, either plan will answer the same purpose. I believe, salivation has sometimes been brought on by the mercury, in the composition of the plaster, which is certainly an objection to it. Mr. Scott's apparatus is generally allowed to continue unchanged for a fortnight, unless much suppuration comes on, and then it is taken off and renewed about once a-week. If inflammation occur, however, it is to be removed, in order to admit of leeches being applied. But when matter forms, I conceive, it would be more cleanly to make use of common splints. I should think, that when there are abscesses, pasteboard, or splints, would be, on every account, preferable to a mass of materials, which are to be removed only once a-week, and under which a great deal of filthy discharge must collect.

Gentlemen, the next subject will be *ulceration of cartilages*.

CLINICAL LECTURES

DELIVERED

At the Meath Hospital, or County of Dublin Infirmary, Session 1833-34.

BY PHILIP CRAMPTON, M.D., F.R.S.,
Senior Surgeon to the Meath Hospital, Surgeon-General to the Forces in Ireland, &c.

LECTURE II.

Fractures—Physiology and Pathology of Bone—Treatment of Fractures.

GENTLEMEN,—The management of fractures of the extremities is among the most ordinary duties which the surgeon has to discharge, and as there are at this moment in the hospital what may be called a very good assortment of injuries of this description, I think I cannot commence our course of clinical instruction in a better manner, than by directing your attention to the cases which illustrate this important department of surgical practice. There is in No. 1, a case of simple fracture of the tibia; in the Female Accident Ward a case of simple fracture of the fibula, two inches above its lower extremity; in the Male Ward, No. 2, a compound fracture of the olecranon; in the Female Ward, No. 2, a compound fracture of the tibia, which for some days threatened to terminate in gangrene. These cases (forming an ascending series in point of importance) are particularly deserving of your attention; and I shall treat of them in the order in which I have placed them.

Before I proceed, however, to treat of those

cases in detail, I shall give an outline (a clinical lecture will not admit of more) of the principles on which the treatment should be conducted, and I shall afterwards illustrate these principles by reference to each individual case respectively. But before I enter upon the subject of the *treatment* of fractures, it will be necessary (in order to make the matter intelligible to the younger part of the class) to say a few words respecting the nature of bone, and the mode in which injuries affecting that part of the animal structure are repaired.

Bones differ in no respect from the soft parts which they support, except in their containing a considerable quantity of an earthy salt (the phosphate of lime), to which they are indebted for their solidity. This substance, secreted from the blood, is lodged in a matrix of organised cellular structure, the basis of which is animal jelly. The whole of the phosphate of lime may be separated by macerating the bone in muriatic acid, and yet the shape of the bone will remain unaltered, or the animal matter may be separated from the earthy part (by fire) with the same result. The vital actions of bone in health and in disease are modified by an admixture of an unorganised substance; all their actions are slow, their growth is slow, and so are their powers of reparation.

The external surfaces of bones are covered with periosteum, a dense, white, fibrous membrane, pierced at different parts of its surface by the blood-vessels, nerves, and absorbents with which the bones are supplied. The periosteum closely embraces the bone, and sends from its internal surface processes which enter the pores, which you observe on the surface of dry bones; through these pores the blood-vessels pass, which contribute to the nourishment and reparation of bone. It is a mistake to suppose that the periosteum is the sole organ employed in the secretion of bone. In the case of Hagan, (compound fracture of the tibia), at present in the hospital, you will see the surface of the bone completely denuded, smooth and white as ivory, on a portion of which, however, you may observe granulations beginning to shoot out. This is conclusive evidence, that bone is not indebted solely to the periosteum for its growth or reparation, and that its own vessels bear an active part in the process. These granulations will gradually secrete bony matter, and thus contribute to the formation of the callus, by which the fractured portions are consolidated. You will see many beautiful examples of this kind in cases of extensive wounds and lacerations of the scalp, where the surface of the cranium is entirely denuded of periosteum, and during the process of recovery the bone will be found studded all over with granulations, the product of its own vessels.

Bones when fractured, without exposure of their surfaces to the air, generally unite by first intention, like the soft parts; but the process of reparation, however, for the reasons

already mentioned, requires a longer time for its completion than solutions of continuity in the fleshy parts of the body. The secretion of the earthy matter is slow, and, before a perfect union can be established, the requisite quantity of phosphate of lime must be deposited by the secreting arteries. The first thing, which takes place after the occurrence of a fracture, is an effusion of blood from the torn vessels; this forms a matrix, into which blood-vessels, from the surrounding parts, begin to shoot. By these vessels a quantity of coagulated lymph, or gelatinous matter, is secreted, and the arteries, which enter this substance, taking on the action of the part from which they are derived, begin to deposit ossific particles. The vessels of the bone and periosteum, whose office is to bring about the necessary reparation, and those in their immediate vicinity (which take on the same action) continue to perform their operations under the influence of an increased, or, as John Hunter used to term it, an ossific irritation of the part, until the bone, for a considerable extent above and below the fracture, is covered with an osseous case; this is the "*provisional callus*" of Baron Dupuytren, to whom we are indebted for the first distinct account of the process which nature employs in the reparation of fractures of the long bones. As soon as union has been effected by means of this newly formed substance, and the fractured extremities have been firmly consolidated, by a process to be afterwards described, all this mass, involving periosteum, cellular substance, and muscles, is gradually absorbed, and a firm bony production, termed callus, cements the fractured surfaces, leaving the continuity of the medullary canal complete, and also leaving the fractured bone without any of that bulbous appearance, which it presented for the first few weeks, but which is always removed when the union is perfectly accomplished. In compound fractures, where the surface of the bone is exposed, the mode of union is different, being effected by a granulation, and if the injury be such as to destroy a portion of the bone, exfoliation takes place, a process which is analogous to the sloughing of the soft parts, but is much more tedious in its operation.

Having thus, gentlemen, given you a general notion of the mode in which nature repairs the injuries of bone, I can with advantage enter a little more into detail. I will not trespass upon your time by stating and discussing the various theories of the union of bone; it will be sufficient to say, that until the time of Du Hamel bones were supposed to be united by what was termed an osseous juice, a kind of liquid, supposed to be contained in the substance of the bone, this fluid becoming effused by the fracture, was supposed to become hard by degrees like plaster of Paris, thus consolidating the fracture, as it were, by a kind of solder.

I believe we are indebted to Baron Dupuytren for the first correct notions on the mode:

in which the injuries of bone are repaired. The unequalled opportunities which the Hôtel Dieu affords of prosecuting pathological inquiries, have not been lost on the French pathologists; and it is due to them to acknowledge frankly the deep debt of gratitude which we owe them for the most valuable contributions which have of late years been made to surgical pathology. The result of the Baron's inquiries have since been confirmed and extended by the experiments of Breschet and Villerme. According to these pathologists, the process of reparation in cases of fractured bones, may be divided into five periods. During the first of these, which extends to the eighth or tenth day, blood is found to be effused from the vessels of the bone, periosteum, and parts in their immediate vicinity. That portion of the periosteum which lies in the effused blood, becomes thickened and so altered in structure, that its texture can no longer be accurately traced through the effusion. The red particles of the blood now begin to be absorbed, and from about the eighth to the twelfth day a gelatinous mass is discovered without any red particles, plentifully supplied with vessels, while at the same time the structure of the surrounding parts is altered, and the muscles, membranous expansions, and cellular tissue, become converted into a greyish homogeneous substance, similar to that which embraces the fracture. This is succeeded by the second period, which extends from the tenth or twelfth to the twenty-fifth day. The general swelling of the limb subsides during this period, and we now can distinguish the tumour formed by the callus, which had hitherto been more or less indistinct. You will now find, that in the situation of the fracture the periosteum becomes thickened, and that exactly over its seat the swelling is greatest. About the twentieth day, if a fracture be examined, a considerable quantity of bone will be observed on the inner surface of the periosteum, but none on its outer surface. I had a series of preparations which beautifully illustrated this point. I regret I cannot at present show them to you, but I can briefly state the particulars which they illustrated.

I purchased a horse, which had suffered a fracture of the humerus, and kept him in a stable for forty days without any treatment, at the expiration of which he was killed, and the arteries of the shoulder injected. In the horse the process of reparation is slower than in the human subject, but it is the same, and the preparation fully illustrated what I have mentioned. The periosteum was thickened to the extent of half an inch, on its internal surface it presented laminæ of new bone, which lay over and bound together several great fissures in the humerus, and with a knife you could strip off the periosteum, carrying with it these flat scales of bone. At one part of the humerus there was a complete case formed by the periosteum, keeping the parts in apposition and forming a kind of cylin-

dric splint. There was also another curious circumstance connected with this case; the gelatinous matter exhibited a high degree of vascularity, and was made quite red by the injection, and in the centre of this, several fragments of bone were lodged, which had preserved their vitality, by means of the medium in which they were placed, for they were injected through the vessels of the part, and appeared to serve as so many centres of ossification. The substance of the humerus itself had also become so intimately connected with this new bony stratum, and the latter formed so firm a mass, that it was hard to say where the surface of the old bone ended and that of the new began. The case, therefore, presented this singular phenomenon, detached bony fragments, still retaining their vitality, and united to the original bone through the medium of a semi-cartilaginous substance.

The third period in the reparation of fractures extends from the twenty-fifth to the fortieth day, when the bony tumour or callus becomes completely ossified both on the outside and inside: it is still, however, lumpy, and forms a separate tumour. But here is a particular point, which was first described by Baron Dupuytren:—if as late as the fortieth day the callus be opened by making a section through the new stratum, we shall find that the fractured surfaces or extremities of the bone itself do not hold the slightest connexion with the callus. The extremities of the bone are only covered with a white flocculent matter, the production of its own vessels; and if you divide the callus you will find that this flocculent substance readily yields, and produces little or no adhesion between the detached parts. In the fourth period, which commences about the fortieth day, the callus becomes more compact, and the intermediate flocculent substance has acquired a greater degree of firmness, still, however, being capable of permitting motion between the fragments, if the support afforded by the callus be removed. In the last period, which extends from the fifth to the eighth or tenth month; the absorbing process is progressive; and, about this time, the tumour formed by the callus is no longer traceable, and the osseous union is perfectly accomplished.

I am describing now, gentlemen, the process of nature in repairing the injuries of bones where the fracture is transverse, the displacement has been remedied, and a proper position maintained during the cure. A different process takes place in cases where the fracture is oblique, and splinters the bone in this direction, and where the splintered ends ride over each other. In such a case, nature is, as it were, balked in her effort. If left to herself, the first thing which she does is to remove by absorption, or round off the sharp projecting extremities of the bone; a quantity of *provisional callus*, which has been already secreted, then unites, and solders the bones together, and remains permanent.

From these facts we may draw some very important inferences. The first is, that it is of the highest importance to effect the coaptation of the fractured bone as soon and as perfectly as possible, in order that a perfect consolidation may ensue. The other inference is, that up to the end of the third or fourth month the provisional callus is the chief support of the fracture, and that, consequently, persons who have just recovered from fractures should be careful in undertaking any kind of exercise or exposing themselves to sudden shocks or falls, which will be likely to produce a fresh separation of the fracture, as the bond of union is at this period by no means perfect. This was the case with Mr. Clarendon, master of the riding school in Brunswick-street. He got a fall from his horse and fractured his thigh-bone, for which he was attended by the late Mr. Gregory and myself, and the fracture went on very well. About the end of the third month, thinking he was quite recovered, he got upon horseback again. The horse which he rode being a spirited animal got frightened at something and made a sudden plunge; Mr. Clarendon clapped his knees firmly against the saddle to retain his seat, and snap went the fracture. He was again confined to bed, and the fracture united firmly, but, owing to some circumstance or other, the union was not so regular as before. There is a third inference which we can derive from this, namely, that where a fracture has been improperly set we may, up to the third month after its occurrence, break and reset it with the most perfect safety, as there is, as yet, no direct union between the bones themselves, they being kept together solely by means of callus. I did this in the case of a child some time since, even at a later period than the third month, with decided success. The child was brought to me at the end of four months with its thigh-bone bent anteriorly (nearly at a right angle); I laid it on a table, and pressing on the thigh with the whole weight of my body, the bone gave way and became straight; in this position I secured it by splints and repeated extension. The child is now four years old and has not the slightest deformity. You see, therefore, the close connexion which exists between sound pathology and successful treatment.

Fractures have been divided into *simple*, *compound*, *comminuted*, *transverse*, *oblique*, and another which I think may be termed *mixed*, in which the fracture is partly transverse and partly oblique, just as when you break a piece of wood, you find that in the outer and superficial portion the solution of continuity is oblique, but as the fracture goes deeper it becomes transverse. The only use of such distinctions is, you will remember, that if the fracture be transverse the fractured portions are easily brought together, and retained in their proper position; but this is not the case if the fracture be oblique. Thus, in an oblique fracture of the tibia there will be a

shortening of the limb and a difficulty of coaptation, from the fragments riding over each other, circumstances which we do not meet with in cases of transverse fracture. Taking the subject in this point of view also suggests some differences in the mode of treatment. If you have an oblique fracture of the tibia, and, in selecting a position, you lay the limb on the side, and find that it rests easy and in a proper manner, without any projection of bone, you may leave it so; but if, after placing it in this position, it bends outwards, and the projecting spiculæ show a tendency to come through the skin, you may conclude that the position is wrong; turn your patient on his back, let the leg rest on the heel, and you will find that the extended posture, aided by the pressure of the heel, will redress the deformity.

Fractures are simple when the bone is broken without being accompanied by such wound or injury of the soft parts as will expose its surface. They are termed compound when a wound extends through the soft parts to the seat of the fracture.

The predisposing causes of fractures are various. Among these old age is one of the most common; the bones of old persons become brittle from the prevalence of the earthy basis over the animal matter. They are also reduced in size by the process of absorption, and hence the marks which exist on their surfaces are more distinct, so that if you take up a dried bone you can make a very tolerable guess at the age of the person to whom it belonged. Extreme atrophy, as in persons who have long laboured under chronic disease, is another circumstance which predisposes to fractures. I knew a gentleman who had a general paralysis for twenty-five years, and gradually lost the use of all his limbs, so as to be perfectly helpless. His sister, one day, while turning him on a sofa with all proper care and gentleness, heard something crack, and on examination the humerus was found to be broken. It was curious, however, that this fracture afterwards united, and continued to do so for the space of ten years up to the period of his death. Rickets is another predisposing cause of fracture, but not at the commencement. But it is at first, (in consequence of its softening and rendering flexible the tissue of the bone,) rather disposed to prevent fracture, but afterwards the bones become brittle, and fractures are of common occurrence. I know a family in which all the children have rickets, one of these, about two years old had his thigh fractured in the act of taking him out of bed. Another of them broke his leg by jumping from a chair. But of all the predisposing causes of fracture, I believe cancer is the strongest. Persons in cancer suffer an extraordinary change in the constitution of their bones; absorption takes within them, their walls become weakened and the medullary canal enlarged, they are capable of being pulverised easily from the slight cohesion of the

particles, and consequently give way on the slightest force being applied.

I shall now, previously to entering on the consideration of the cases at present in the hospital, make a few remarks on the general treatment of fractures. In the treatment of fractures, you must be aware, that there is a perfect analogy between the soft and hard parts. The first principle on the treatment of injuries of the soft parts is to effect a perfect apposition of the separated surfaces, which in most instances can be much more easily effected by relaxing the muscles than by dragging the parts forcibly together by means of sutures and bandages. In the same way fractures are not to be reduced by violence, but by the aid of a proper position. The next indication in the treatment of fractures is to allay irritation and inflammation. John Hunter speaks of adhesive inflammation as the means by which injuries of various parts of the body are frequently repaired without the occurrence of a purulent discharge, but if this process were merely inflammation, it would retard rather than promote the reparation; we should rather look upon it as a natural process accompanied, no doubt, by heat, increased vascularity, and consequent redness, but if inflammation, properly so called, actually takes place, it proves rather an obstacle to the cure, for if inflammation attacks the surfaces of a wound, all the sticking plaster you can apply to bring about adhesion will effect nothing. But to return to the subject of adhesion. The merit of the relaxed posture in the treatment of fractures has been attributed to Mr. Pott, but not with justice, as it is strongly insisted on by Fabricius and Hildanus. The rule, however, is liable to many exceptions, to some of which I have already adverted, and others I shall notice as we proceed to the treatment of fractures in detail.

You will find many rules laid down in books for the purpose of enabling you to ascertain the existence of fractures, and it is said that you can know them in various ways, by the eye, the ear, and the touch. Of these the eye and the touch are the senses most relied upon; you will also on some occasions use the ear in ascertaining the existence of crepitus. But there are many cases where it is perhaps worse than useless to look for crepitus, for instance it is of very little consequence to know whether it exists or not in case of fracture of the neck of the thigh bone and by endeavouring to ascertain its existence, you will incur the risk of derangement. There is frequently but very little derangement in such a case, the strong fibrous membrane which invests the neck of the bone sometimes keeps the parts in apposition. If, in case of this fracture from an anxiety to show whether fracture exists or not, you rotate the limb roughly, you may separate the parts still farther, tear away what remains of the fibrous membrane, so that the limb becomes retracted, and the patient is thrown into violent torture. There are many instances

of fracture in which a single glance will afford you sufficient information; in nine cases out of ten you will know the existence of fracture of the leg from its appearance, and the same thing holds good in the case of the fore-arm and arm. Add to this the distortion of the limb, and impossibility of using it, of performing certain motions, and you will have sufficient evidence of the existence of fracture, without inflicting on your patient additional but useless pain.

I will resume this subject at our next meeting, but before I conclude, I would direct your attention to the case of a woman in the small ward with fracture of the fibula, and I wish you would continue to observe it for the next two or three days, as I shall allude to it more particularly on Friday.

ON THE EFFICACY OF THE *SECALE CORNUTUM* IN *HÆMORRHAGE* AND *LEUCORRHEA*, AND ON ITS EFFECTS IN *GONORRHEA*.

BY G. NEGRI, M.D.,

*Read before the Medical Society of London
Monday, November 25, 1833.*

GENTLEMEN,—Since the action of *secale cornutum* on the uterine system attracted the particular attention of obstetric practitioners, and has been successfully employed in cases of long protracted labours, Dr. Atlee, of Philadelphia, Professor Bigieschi, and Dr. Ballardini in Italy, as well as Dr. Guillemont in France, have recommended it as the most efficient remedy to arrest menorrhagia, when occasioned by want of uterine contraction after labour. Dr. Shallcross recommended it also in those uterine hæmorrhages, which originate from a partial detachment of the placenta; whilst Professor Dewees expressed his belief, that it might be efficacious in hæmorrhages in general. In the *London Medical and Physical Journal* for May, 1829, a case of menorrhagia, cured by that remedy, after three months' trial, was related by Dr. Marshall Hall, who found it also beneficial in leucorrhœa.

From all these facts Dr. Spajrani, who had already successfully employed the ergot of rye in several instances of leucorrhœa, was induced to try its efficacy in other uterine hæmorrhages, not immediately connected with parturition. After the favourable result of his first experiments, he extended the use of the ergot of rye to any other hæmorrhages proceeding from different mucous textures, both in male and female.

The result of Dr. Spajrani's observations on this subject was published in the fasciculus for March, 1830, of Omodei's *Annali Universali di Medicina e Chirurgia*. In that interesting publication are related eight cases of menorrhagia; four cases of what he calls uterine

congestion; two of epistaxis; five of hæmoptysis; and two of hæmaturia. (A correct account of this essay was published in *The Lancet* for February, 1831).

Another publication, on the same subject, appeared in the following number for May and June, 1830, by Dr. Pignacca. It contains two cases of menorrhagia and two of hæmoptysis, successfully treated with the *secale cornutum*; and in the fasciculus for February and March, 1831, of the same Italian periodical, two other papers were published, one by Dr. Gabini and the other by Dr. Bazzoni. The first contains three cases of menorrhagia; one of hæmatemesis; one of pneumorrhagia; and two of epistaxis, one of which occurred in a woman affected with acute scurvy, and accompanied with all the other symptoms of what has been called *purpura hæmorrhagica*. Dr. Bazzoni's publication contains an account of eight cases of leucorrhœa, treated with the ergot of rye, in which it afforded great benefit in arresting the white discharge, even in instances considered of an incurable nature from organic malignant disease of the womb.

We have read since, in *The Lancet* for March 10, 1833, an account of an "admirable essay" on the use of ergot of rye in menorrhagia, published in the *Bulletin Général de Thérapeutique*, by MM. Trousseaux et Maisonneuve.

A case of hæmoptoe in a man, cured by the same medicine by Dr. Lanyon, was published in *The Lancet*, April 13, 1833; and another of menorrhagia in a woman, aged 60, by Dr. Bright, was lately published in *The Lancet* for June 15th, together with an article by Mr. H. A. O'Slea, "on the anti-hæmorrhagic effects of the ergot of rye on the male," in which he states, "that, in corroboration of what was published by Dr. Lanyon, he (Mr. O'Slea) employed that medicine with the same view for the last two years, with *invariable success*," and concludes, that "the adoption of this practice arose from reading an article on the same subject, published in a number of *The Lancet*, some time in the year 1831."

In all this time we had ourselves a favourable opportunity of trying the efficacy of the *secale cornutum* in different instances of menorrhagia and leucorrhœa; and with the view of ascertaining its *modus operandi*; we tried it also, we think for the first time, in gonorrhœa, both in female and male. In bringing before this Society the result of our experience on this subject, it is not to believe we intend to proclaim the *secale cornutum* as an *infallible* remedy, or as a *certain* specific against those diseases, and that nothing else may be required but to exhibit *indiscriminately* large and frequently repeated doses of it to obtain a speedy cure. It would then happen of the ergot of rye, given for those complaints, what did happen before of it, when administered in cases of protracted labour; in the hands of some practitioners it will succeed, while in the hands of others it will fail, or be even injurious.

About the method of administering the *secale cornutum*, Dr. Spajrani laid down the following remarks:—"To obtain a speedy and favourable effect from this remedy it must be of the best quality, otherwise it will fail. (This fact was evidently proved in one of the cases related in his paper.) The dose of the remedy must be generous, often, and regularly repeated. If the hæmorrhage be very violent it must be given from vi. to x. grains, even every ten minutes, till the hæmorrhage ceases; if not so violent, every two hours, or at longer intervals." He ordered it generally in powder, but he used it also in pills and in decoction.

When we began to employ the ergot of rye, having no personal experience of its therapeutical properties, we used it in smaller doses than those recommended by Dr. Spajrani, and we are perfectly convinced, that in some instances it failed, or its efficacy was retarded for this very reason.

The effects on the general system, which followed the exhibition of the *secale cornutum*, have not been constant, or the same in the different individuals who took it, but *never of an alarming character*. The greater number of patients were complaining of giddiness and headach, which followed in general only the first doses of the remedy, and did not last long. Few were complaining of sickness, and others of a general sense of prostration, *all over from the head to the top of the fingers and toes*. Some women, who had both menorrhagia and leucorrhœa, complained of pains round the hypogastric region and liver, and some even expressed it "as a sense of bearing down of the womb." A woman, who had a chronic ulcer on her right foot, complained of excessive pain in it since she began to take the *secale*, and others complained of pains along the thighs and legs. But others, on the contrary, felt no inconvenience at all from larger and long-continued doses of the remedy, although the drug was the same, and manifested its beneficial efficacy on the disease for which it was used. In two or three cases of menorrhagia only, the loss of blood, and the pains round the hypogastric region and loins, were remarkably increased by the action of the remedy on the uterine system. Therefore, in instances of this kind, we bled our patients first, and then gave the *secale* with the best success. On this point of practice we followed the suggestion of Dr. Bazzoni, who stated in his paper, that "in hæmorrhages the *secale cornutum* may be useful, whether they are active, or passive, primary or secondary, but its *proper indication is in their passive state*; although, says he, it may be of some service in the opposite state, *still it will be more prudent to have it preceded by blood-letting*." For the same reason, if the strength of the patient would not allow any further loss of blood, we employed moderate doses of tart. ant. when it was necessary to allay the over-excited action of the heart, or arterial system, or we used mild opening medicines where an habitual state of costiveness might.

have been considered as the principal cause of irritation, and local congestion of the uterine system; these simple means succeeded sometimes in arresting the hæmorrhage without any want of other therapeutical agents.

Of its peculiar *modus operandi* we shall speak after having exposed the facts which enabled us to draw some conclusions, as far as it is possible on that subject. We shall now proceed to relate the most important cases of hæmorrhage which were treated with the *secale cornutum*.

CASE I.—Menorrhagia.—Ann Beteux, age 35, married, was admitted to St. John's Dispensary, 19th of January, 1832. She had been ill for a long time with menorrhagia, and had been under different treatment till the 9th of April, but without any permanent relief.

On the 16th of April the hæmorrhage having appeared again, we thought proper to try, for the first time, the effect of the *secale cornutum* in this case, and five grains of the powder were ordered to be taken three times a day. The hæmorrhage from this time gradually diminished, till the 10th of the following May, when it entirely ceased.

May 14th. She feels a great deal better, and has no more pain in the loins and groins. The powders were continued twice a day till the 24th of May, and she was afterwards discharged cured.

CASE II.—Menorrhagia.—Ann Marshall, age 30, married; was admitted on the 14th of May, 1833, labouring under a very profuse menorrhagia. Her pulse was quick and sharp; had great pains round the loins and hypogastric region, which was very tender. She was ordered to be bled to xiv. oz., and saline aperient powders were prescribed.

17th. The pains round the loins and groins are better; her pulse is softer, but the hæmorrhage is still going on with great violence. Five grains of the *secale* to be taken three times a day.

21st. She feels a great deal better; had no hæmorrhage since the 19th, viz. two days after she began to take the *secale*. The same powder was repeated, to be taken twice a day, and was discharged the following day of attendance.

CASE III.—Hæmorrhage from the rectum following suppression of the catamenia.—Hannah Paton, age 21, single, was admitted on the 12th of July, 1832. Eight months ago felt quite well. Has not been regular the preceding month, but had some pain in the groins and loins, with great general debility. These symptoms were followed by hæmorrhage from the rectum, which continued at intervals up to this day. Had previously taken some opening medicine without any relief. Five grains of the *secale* to be taken every four hours.

16th. Since she has begun to take the powders, finds the hæmorrhage much abated. Pergat.

23rd. Has had no hæmorrhage since the 20th. The menses returned on the 21st, and she feels now quite comfortable. The powders were repeated, to be taken occasionally, and she was afterwards discharged.

CASE IV.—Excessive Menstruation.—Mary Forest, age 40, married, was admitted on the 19th of July, 1832.

She has had for the last eighteen months a very profuse bloody discharge at the menstrual periods, which never, till lately, continued longer than five days. She was regular about three weeks ago, when the hæmorrhage reappeared with great violence, and continued unabated for the last seventeen days. Has pain in her back and groins, and complains of general debility. Her pulse was very quick and empty. Five grains of the *secale* to be taken every three or four hours.

23rd. She feels much better. After taking three powders she had violent headache and giddiness, which kept on increasing as she took them, and felt a kind of contraction, or, as she expressed it, "a sense of bearing down of the womb." She continued the powders up to the night of the 20th. The hæmorrhage entirely ceased on the morning of the same day. After omitting the powders her head got better. The *secale* was ordered in pills, and in smaller doses, only to be taken twice a day. As she was complaining of great general debility, a little camphor mixture, with small dose of the sulphate of quinine, was ordered to be taken occasionally in the course of the day.

30th. She is going on better; had no more hæmorrhage. Her bowels being costive, opening pills were ordered, and wished to have a blister behind her neck to relieve her head. She was discharged the following day of attendance.

CASE V.—Menorrhagia following Leucorrhœa.—Sarah Scanterbury, age 47, married, was admitted on the 26th of July, 1832. Has had leucorrhœa as long as she can recollect; has miscarried nine times; her last pregnancy was about three years ago; a month since was unwell, and the menstrual discharge was unusually profuse; it returned again in a fortnight, and it has reappeared this morning, July 26th, this being the third time within five weeks. She feels weak, and has pains in her groins and back; no medicine has been previously taken. Five grains of the *secale* to be taken every four hours.

30th. The bloody discharge continued from Thursday, the 26th, till Saturday, the 28th, when it entirely ceased. It has not returned, and she feels now much better. The *secale* was suspended, and only some cremor tartar. ordered to be taken as an imperial drink.

2nd. She is going on very well. The same saline aperient was ordered to be taken

taken occasionally, and was discharged the following day of attendance.

CASE VI.—*Hæmatemesis*.—Elizabeth Pilcher, aged 10, in June, 1832, was in good health. Her illness was caused through having been violently pressed round the waist by a man, who frightened her very much. This produced pain in the right hypochondrium, extending towards the epigastric region, and was followed by a sense of sickness at first, then vomiting of the contents of the stomach, and afterwards of pure blood. She had continued in that state up to the day of her admission, the 30th of July, 1832. If pressure is made over the right hypochondrium, which has been very tender since the commencement of her illness, the hæmorrhage ensues immediately. She was not under our care till the 10th of the following month of September, but had not found any relief from the usual means which were employed from the time of her admission. I thought this a good case to try the effect of the secale; therefore, after having used some mild opening medicine, on the 13th of September, three grains of the secale were ordered to be taken three times a day.

This remedy was repeated the 17th and 20th of the same month, but without producing any effect in arresting the hæmorrhage. It was then discontinued, and other means were adopted. The greatest benefit was obtained by the sulphate of iron mixed with kino. On the 28th of February, 1833, she was discharged, having been more than a month quite free from any hæmorrhage.

She remained well for about ten days, when having accidentally struck with violence her right side against a chair, the pain in the right hypochondrium and vomiting of blood returned. She came back in consequence to St. John's Dispensary on the 7th of March, 1833, and was admitted under our care. Different remedies were employed, which were found beneficial on the former occasion, but without obtaining any good effect on the disease. We then thought proper to have recourse again to the secale cornutum, but administered in larger and more frequent doses. Therefore on the 28th of March we ordered six grains of the secale to be given every third or second hour. After having taken six powders, the sickness, the vomiting of blood, and the pain in the right hypochondrium left her. She continued taking them at longer intervals for several days, without giddiness or any other unpleasant symptoms arising from the medicine. Her pulse appeared stronger, and her countenance more animated and florid than before. She omitted once taking her powders for a short time, and the sensation of sickness and the pain in her side returned, but was very soon relieved by having recourse to the same remedy. The powders were continued, but only night and morning, from the 1st to the 14th of April. On the 15th they were entirely omitted, as our patient felt herself

quite well. April 29th she was discharged cured, and has not yet returned.

CASE VII.—As another instance of hæmatemesis, we shall relate, with Dr. Macmichael's permission, one which occurred in the Middlesex hospital.

Lucy Haselton, ætat. 21, single, was admitted into the Middlesex Hospital on the 21st of September, 1830, under Dr. Macmichael's care, King's Ward.

She was complaining principally of great tenderness over the right hypochondrium, extending towards the epigastrium; she had sickness, with vomiting of a dark fluid mixed with blood, greatly coagulated. Local bleeding, and different astringent remedies were employed without success. On the 27th of November, Dr. Macmichael was kind enough to prescribe for her, at our suggestion, the following powder.

R. Pulv. secalis cornuti gr. vi. ter die sumend.

29th. The patient was better, and the same remedy was continued.

30th. The hæmorrhage having ceased, and the pain over her right side greatly diminished, she was discharged, and only kept as an outpatient. The powder was ordered to be taken only twice a day.

December 2nd. She stated she had not seen any more blood, and was going on well.

CASE VIII.—*Hæmatemesis with enlarged spleen*.—Eliza McCulloch, ætat. 10, admitted on the 3rd of October, 1833. About four years ago she had hæmorrhage, which was considered to come from the lungs, and has continued at intervals ever since. The blood is generally of a red colour, and is never mixed with food. The hæmorrhage is usually preceded by pain and uneasiness at the scrobiculus cordis, and nausea; the blood comes up in a way different from expectoration, by an effort similar to vomiting; she has afterwards a very unpleasant taste in her mouth. The fluid brought up in this way has been repeatedly brought to us. Being collected in a glass vessel, had more the appearance of a bloody lymph than of pure blood. It remained quite fluid, and had a peculiar disagreeable odour. The quantity emitted at each time has never been very considerable. She has pain on pressure being made at the scrobiculus cordis, and if on the right extremity of the stomach, the pain runs across to the left. At the left hypochondriac region there is great prominence, and she complains of frequent pain there. She has often rigors at night, and afterwards perspires very much. She never had a cough or expectoration for any length of time; she is subject to violent fits of passion. Her illness has not weakened her much; her appetite is good, and she sleeps well; her complexion is flushed.

Although she had been admitted on the 3rd

of October, it was only on the 17th we ordered about three grains of the *secale cornutum* to be taken every second hour.

21st. The vomiting of blood is diminished, and did not suffer any inconvenience from the regular use of her medicine.—Pergat.

24th. The vomiting of blood still continues as much as before.

R. Pulv. secalis cornuti gr. vi., tertia quaque hora sumend.

November 4th. She has not brought up any blood for the last three days. The powders were then repeated, to be taken only night and morning.

November 11th. She has had no more hæmorrhage, although she has not taken any more of the powders for the last few days. She feels quite well; and having carefully examined the left hypochondrium, under her dress, no more prominence could be felt or seen on that side. She was then discharged cured.

CASE IX.—*Hæmorrhage from the rectum*.—Mary Smith, æt. 30, was admitted on the 29th of April, 1833. Had then a chronic diarrhoea, and afterwards hæmorrhage from the rectum took place after each motion; this has continued for a fortnight, and she thinks she has passed more than a tablespoonful of clear blood after each stool. The diarrhoea was very much reduced, principally under the use of small doses of *hydrargyrum cum creta* and pulv. *ipeacuanhæ*.

On the 17th of June, having for the first time complained of this hæmorrhage, and being on this day more copious than usually, we thought proper to try in this case the effect of the ergot of rye. Six grains of the powder were ordered to be taken every three hours.

June 18th. The patient was a great deal better. She told us that from the time she began to take the medicine, she had no more hæmorrhage, although she had two motions this morning. The medicine was continued, but at longer intervals. On the 27th of June she was discharged cured.

CASE X.—*Epistaxis*.—Sarah Hodges, æt. 62, of a leuco-phlegmatic habit, was admitted on the 19th of August, 1833. She was seized with epistaxis on Thursday evening, three days previous to her admission. On the following evening (Friday), at about eight o'clock A. M., the hæmorrhage returned, and continued for half an hour, when she applied to a surgeon, who put plugs into the anterior nares, but the bleeding continued through the posterior the whole of the night, more or less. On the following morning (Saturday) she was bled from the arm to about a pint, and took some opening medicine. The hæmorrhage, however, continued at intervals all that day and throughout the night, but not so violently as before.

On Sunday morning the hæmorrhage, after having ceased for a little while, returned about the same hour as on the preceding day, and continued more or less all the day, and in the evening it was very much increased, and went on bleeding at intervals almost all the night.

On Monday morning (August 19th), about noon, the bleeding came on very freely; she thinks she lost about half a pint of blood in a quarter of an hour.

When we saw her it was about one o'clock P. M., at which time the hæmorrhage was very active. She was very pale and weak, her pulse quick and small. Six grains of the *secale cornutum* were ordered to be given immediately (one o'clock P. M.), and to be repeated every quarter of an hour. She was directed to sit down in the apothecary's room, with the view of ascertaining the result.

At a quarter past one the hæmorrhage was very much abated; she was then complaining of being very faint; a second dose was given, and five minutes after, namely, twenty minutes from the first exhibition of the remedy, the hæmorrhage had entirely ceased. Another powder was given at half-past one, and a fourth at two o'clock. She was then sent home, and directed to take one powder only every hour till six o'clock in the evening, and if no hæmorrhage re-appeared to take one of them every three hours.

August 20th. We visited the patient at her own house, and found her lying down comfortably. She stated that she had been free from hæmorrhage since she took the second dose at the Dispensary, and now feels only very weak. The powders were continued at longer intervals.

22nd. She was well, and had seen only a few drops of blood the same day I visited her, after having pinched her nose, but ceased directly after taking one of the powders. No remedy was ordered. She returned on the 19th of September, when, being quite well, was discharged cured.

This case was witnessed by our colleagues, Dr. Ryan, Mr. Jenkins, and Mr. Nettleford, the surgeon-apothecary of our Institution, who gave the medicine himself to the patient, and watched over the case.

CASE XI.—*Hæmoptoe*.—Jeremiah Sams, æt. 20, a cabinet-maker. Four months previously he had a cough, with a slight expectoration in the morning, which was generally of a greenish colour. Six weeks ago he observed the expectoration to be tinged with blood; this continued for a week; then he began to bring up about a teaspoonful of blood every morning, and continued so for the last two weeks. The hæmorrhage was neither preceded nor attended by any considerable aggravation of his cough, and only occurred in the morning. He had also some difficulty of breathing when making some exertion. His complexion is very pale. He was admitted on the 3rd of October last, and as there was

not present any symptoms indicating the existence of an inflammatory action, requiring more active means, six grains of the *secale cornutum* were prescribed, to be taken three times a-day.

Oct. 7th. After having taken his powders for two days the hæmorrhage diminished, as well as the cough. Has had no giddiness or any other extraordinary symptom from taking his powders. The remedy was repeated, and shortly afterwards the hæmorrhage ceased.

17th. Had a slight return of the hæmorrhage for two or three days, but only once in the morning.—Pergat.

24th. The hæmorrhage ceased entirely from the 21st. The cough and the difficulty of breathing is a great deal less.—Pergat.

28th. On the 26th he saw again a very little tinge of blood in his spittle. Cough a great deal better.—Pergat.

Nov. 1st. Has had no more hæmorrhage; his cough is now very slight. No remedy.

For the two following cases we are particularly indebted to our friend, Mr. E. Nettleford, the surgeon-apothecary of our Dispensary, who had also the kindness to write down the history of almost all the former cases.

CASE XII.—*Hæmoptysis*.—"Mrs. Clarkson, æt. 33, married, a private patient. Had not been in good health for the last five years, in consequence of rupturing a vessel in her chest. Since this accident she had a cough, which, together with the hæmorrhage from the chest, and sometimes from the nose, has continued up to the present time (April 4th, 1833,) with but slight intermission; indeed, for the last fortnight she has had hæmorrhage from the chest every day. Thinks she might have lost this morning about half a teacupful of blood. Her cough is very troublesome; has great palpitation of the heart, and giddiness.

"April 4th. Six grains of the ergot of rye were ordered to be taken every second hour.

"5th. Rested well last night. This morning her pulse is quick, but soft; the cough less, and she expectorates freely. Has had no hæmorrhage since taking the above powders, of which she has taken sixteen. The giddiness is less, and she feels much relieved.

"6th. No hæmorrhage has occurred; her cough is better; pulse full, quick, and rather sharp; tongue white. She is feverish, with pain in her side, and this is usually followed by the bleeding, which she thinks will soon come on.—Continue the powders every hour.

"7th. The pain in the side left her in the night, after which she slept well. Has had no hæmorrhage; feels very weak; pulse soft, and moderately quick; is not giddy. The hæmorrhage has never left her so long before for a considerable time. Her cough, she thinks, is certainly better, and has experienced much relief from the medicine.—Continue the powders every second hour.

"11th. The hæmorrhage has not returned; her pulse is soft, and much less frequent than

before she took the *secale*; the palpitation of the heart was also less troublesome, and her cough is much easier now than before.—Twelve grains of the *secale cornutum* to be taken every second hour.

"22nd. Has had no hæmorrhage since taking the *secale*, and its increased dose has produced no unpleasant symptoms. She finds it relieves her cough considerably; but, as it is accompanied with hectic fever, there appears to be but little hope of her being cured of it. The *secale* has certainly abated the hæmorrhage, which is all that, in such a case as this, could be expected, and at the patient's desire it is continued.

"No return of the hæmorrhage up to the present day (April 29th). She died some time afterwards from consumption, but had never any return of the hæmorrhage."

CASE XIII.—*Hæmoptysis with Leucorrhœa*.—"Mary Smith, æt. 39, widow; has not been in good health for the last three or four years. The catamenia have not appeared for the last ten months, and has had leucorrhœa ever since, with pains in the loins and over the abdomen, and frequently the globus hystericus. She had a cough last winter, which soon left her, and does not remember having had any before.

"From this time has been free from any complaint in her chest till the last five weeks, when she has had a cough ever since, which at times distressed her very much. Three weeks ago, after coughing violently, she spit blood, and continued to do so for two days. When the hæmorrhage ceased she had pain and giddiness in her head. A week afterwards the spitting of blood returned, and went on for two days. She thinks she lost altogether a good sized teacupful. Did not spit blood again till last Friday, April 26th, namely, at the end of another week, and continued spitting for the whole of that day. Her cough was very violent, her chest painful, her breathing quick and difficult; was very thirsty; she felt hot and feverish; and the leucorrhœa was in the mean time very profuse.

"On the following morning, after having taken some castor oil, six grains of the *secale cornutum* were ordered to be taken every hour. Two days afterwards she was admitted to St. John's Dispensary.

"29th. After taking six powders her chest became easier, her cough was much relieved, and the spitting of blood ceased, as well as the leucorrhœa. She has now taken sixteen of the powders, and has had neither hæmorrhage or leucorrhœa since eleven o'clock P.M. of last Saturday (the 27th), after having taken six doses of the *secale*. Her cough is now very slight; pulse 77, easily compressible; bowels open. Since taking this medicine she has had less giddiness, but feels very weak and faint.—Continue the powders.

"May 2nd. Has had neither spitting of blood nor leucorrhœa. Her chest feels easy, and she,

though but little; pulse 70, soft; tongue clean and moist; bowels open; is not thirsty; skin cool and soft. Has had a little pain in the back and loins, but very slight compared to what she had before. She finds herself much stronger. Her foot is less painful. (She has had an ulcer on the right foot for more than a year, which circumstance she did not mention at first, which has pained her excessively since she began to take the secale.)

"5th. No hæmoptysis or leucorrhœa since April 27th. Her cough is troublesome sometimes, but it is much better than it was; pulse 65, soft and small. She has now taken fifty-four six-grain doses of the secale. Since she has found herself so much better she has taken it only three times a-day. The giddiness has quite left her, and she is now free from pain.—Pergat.

"9th. As she feels so much better, and has been now a considerable time without either hæmorrhage or leucorrhœa, the secale is discontinued, and she was afterwards discharged cured.

Note.—"I have been attending this patient at her own house for a bad leg, and she has had no return of the hæmorrhage.—Nov. 1st. 1833."

For the two following cases I am indebted to my colleague, Dr. Ryan.

CASE XIV.—*Hæmorrhage from the gum, in consequence of the extraction of a tooth.*—"A delicate looking man, aged 32, a carpenter, had the left canine tooth of the upper jaw extracted, and the operation was followed by profuse hæmorrhage. He applied at one of the large hospitals for relief, and was desired to press a piece of sponge into the socket of the tooth. He did so without any benefit. He then applied to Mr. Packer, surgeon, at Hoxton, who recommended him to me. On examination I found a coagulum, about the size of a large walnut, over the alveolar process, but there was still some oozing of blood.

"I ordered him the secale cornutum, in the manner prescribed at St. John's Dispensary, desired him not to remove the coagulum, and wrote to his surgeon, that in the event of further hæmorrhage, to plug the alveolar process with a piece of cork, but should this fail, to apply Ruspini's styptic, or the actual cautery, and, finally, that the carotid ought to be tied sooner than allow the man to die.

"Mr. Packer called on me next day, to express his astonishment at the success of the secale, as it had completely arrested the flow of blood; and he since informed me, that no return took place. I was aware that Dr. Spajrani had removed the coagulum in a case of epistaxis, and encouraged hæmorrhage, and stopped bleeding with the secale cornutum; but I did not consider myself justified in adopting his practice, as the man had lost a great deal of blood, and was very much debilitated."

CASE XV.—*Menorrhagia followed by metritis.*—"Mrs. Davis, æt. 23, of middle stature, married for two years, has had no family, and was admitted a patient at St. John's Dispensary, Sept. 18, 1833, under the care of Dr. Ryan. She suffered from dysmenorrhœa before her marriage, which was very much aggravated subsequent to her change of life. At present she suffers from menorrhagia, accompanied by excessive pain and a discharge of coagula. She was ordered 3j. of secale cornutum, divided into ten powders, one to be taken three times a-day. In three days the uterine discharge ceased, but well-marked metritis supervened, and was removed by the ordinary treatment, venesection, leeching, purgation, &c. Mr. Nettleford saw this case also, and attended the patient at her own residence."

These are the most remarkable instances of hæmorrhage successfully arrested by the use of the secale cornutum, which we thought proper to communicate to the Society. We had, indeed, several other cases of menorrhagia, but we considered them less interesting than those of hæmorrhage from other mucous textures, entirely unconnected with the uterine system. The above facts appeared to us of such a practical importance to deserve the particular attention of the medical profession. Perhaps they might be found not so numerous as to justify any general deduction from them, but if the facts, published by other practitioners, and in other countries, should be taken into consideration, it will be found that the anti-hæmorrhagic property of the ergot of rye has been sufficiently established, to induce others to repeat the same experiments; and, if judiciously employed, we dare to say, with a similar result.—See report of the Medical Society.

LIFE AND ORGANISATION.

BY J. B. SLADE, A.B., M.D., &c., TEIGNMOUTH.
Late of the Sussex and Brighton Infirmary.

To preserve the composition of the animal body, it is only necessary that creatures should provide those articles of nourishment which Providence so bountifully supplies; but when we consider the complexity and wonderful mechanism of the body, the continuance of function for years together, without occasioning fatigue either to that or to the mind, we cannot but feel great interest in discovering the real interposing and essential cause, the being or principle which produces that function, and which gives animation, uniformity of structure and vigour to the animal kingdom.

Man alone has the power of observing all these several phenomena, and by his natural enterprise and curiosity to trace some con-

nexion between them and their cause. Now it is upon the cause which men differ; the effects are objects of their senses, the existence of which none but an idealist would pretend to doubt; but some persons being unwilling to acknowledge that spirit exists in the body, naturally believe that animation and function result from the ingredients or organs of the body, but what the fabricators of this theory, or rather hypothesis, consider life to man, or whether they consider it to consist of motion, as the result of organisation, I am unable to say; at all events the premises are absurd, and the inferences deduced from them must be of necessity the same. However the object of the following pages is to show that the cause of animation and animal function is spiritual, and that it is not the nature of matter, however refined, to produce the several actions and events which take place in the animal system, that no being can create itself, or be deprived of any essential property, or assume a character different from that in which it was created, or act in opposition to itself, and yet remain in existence. These are facts that admit of no dispute, and the principal truths upon which the immaterialist would ground his arguments are, that an effect, whatever it may be, cannot result from that which has no power to operate; that a cause must be an operative being; that an operation must precede that which is produced; and that while a being, whether of matter or of spirit, is independent of its operation, an operation, whatever it may be, and whatever it produces, must be independent of that supposed to be produced. The philosopher is best able to understand what causes are, and to show the extent of their powers, and how they operate, but none appear much less abstruse than those which animate and organise matter, and render it mechanical. But admitting our ignorance of the cause of function and animation, we know by facts that a cause exists. It is impossible to perceive effects without believing in the existence of a being capable of producing, and to suppose an effect existed independently of a cause, is to suppose it to be the cause or creator of itself. Besides, every action, whether it take place in the body or not, *must* result from some active being. The whole universe, every operation, substance, principle, power, and indeed every thing that can properly be considered as finite and natural, are effects. Nature in her stu-

pendous whole is an effect, and therefore is but a name for an effect. This, however, does not exclude the fact that life is the cause of function, or that an operating and attracting property in bodies is the cause of motion, or that chemical affinity is the cause of changes in the qualities of matter. *All* is an effect of one great cause, the Creator; and it is by effects, whether immediately from the first source, or from intermediate sources, that we obtain the greatest part, if not the whole, of our knowledge; but when trusting to conjecture, which we do in attempting to explain immaterial existence and the connexion between it and organisation, we may still doubt the correctness of our judgment on such points; and although unable to comprehend the imperishable arcana of Nature, we must not reject inquiry altogether, for what have not the philosopher, the naturalist, and the physiologist accomplished by their unceasing perseverance. Yet how much soever we may presume on our attainments, it is certain that nothing short of infinite wisdom can unravel every mystery, or understand the constitution of every attribute in creation, and the more deeply we carry our researches, the more we become convinced that the objects of our attention are evident proofs that an essential Deity is the sole existing cause of their creation, preservation, beauty, harmony, and every other conceivable quality belonging to them.

By anatomy we discover how the organs in which the functions are carried on, are situated, and by physiology and chemistry we comprehend their uses and the character of the elementary qualities and particles which constitute them; yet to say that the organs, or their situations, uses, or composition can be the cause of function; implies that such organs, their situation, uses, and composition are not produced by function, nor by life, but by some inherent powers which they possessed previously to there being any occasion for function or for life; but the natural state of matter being rest, and the nature of all matter being the same whether in the form of organisation or of clay, how can function (from which such mysterious developments accrue, and in which is concentrated some of the greatest and most delicate phenomena) result from organisation. Matter, in the time of a functional performance, is certainly in motion, but it is erroneous to conclude that because an organ moves, it is

naturally or *virtually* possessed of means capable of producing either the principle or the act of life, and whatever is not natural to matter at one time, and in one part, must be so at all times and in every part. Hence to suppose that life, or even function, results from organisation, when that organisation is not capable of producing, is contradictory. It is certain that matter can move by means of attraction, chemical affinity, repulsion, gravitation, electricity, and many other peculiar combinations, but such motions are not effected by any essential attributes in the parts moved; besides, the natural immoveability and incapacity of the organs are fully illustrated in the instance of death; but if, for argument sake, we suppose function to be the consequence of electricity, or of any attracting or repelling means, or if these means, or either one of them, constitutes function, what, we may ask, animates those particles which are instrumental in causing function? It is from the great power and mobility of electric fluids, that life has been considered of the same nature, but admitting that either of these means may constitute function, it cannot certainly give animation, which is something more than the result of mechanical motion, and if there be a principle of animation which does not emanate from the body, we may believe that principle to be capable of acting and of producing function at the same time, and when function can be proved to consist of, or result from, one repelling particle repelling another, one attracting particle attracting another, from the laws of gravitation, or from chemical means, it will be proved that the elements and all nature possess life, and that the chief or sole causes of motion in the animal frame are repulsion, chemical actions, attraction, and gravitation.

We find that organs are modelled and arranged differently, and that the same qualities do not enter their composition, but how can these wonderful events be produced by any of the above means, or to what else can they be attributed, but to a super-added principle, distinct from organisation? or what is capable of arranging, preparing, assimilating, and subtilising matter, and giving it an organic place in existence, but vital spirit? and admitting the cause to be spirit or life (for I understand the epithet in no other sense than as spiritual), we may ask how such a principle is enabled to fulfil such important

ends. We find, moreover, a succession of events and changes kept up, and innumerable parts and fluids preserved in motion, but we cannot find, either from reason or analogy, that such phenomena can be carried on by any inherent capacities of any part of material nature. That organisation, or the peculiar and varied states of the organs, the chemical and mechanical actions and changes, may assist life in determining the result, is highly probable, but that it should, independently of a superadded principle, be the primary and efficient cause, is not probable; besides, it would be ridiculous to suppose that a secreted fluid, or any other animal matter, results from the organs, when they cannot result but where life is. True, we know but little of the laws which regulate the organic economy, and we should know still less if a principle distinct from organisation were not considered the principal cause; and to think that the cause of animal processes rests with the conformation of the organs, or results from the mere refinement, delicacy, or any other state of organisation; or to suppose that any textures, say those of the eye, as being some of the most delicate, could organise and animate themselves, is not materialising this principle, but absolutely denying at least the use, if not the existence of such a principle. The cause is life, which does not result from the parts; and to have a proper notion of this cause is to have a proper notion of immateriality.

Further, all organs are formed from a fluid, and every such fluid is a selected portion of aliment; and if their peculiar characters were the production of any part of their nature, of what use would be life, which is the only principle capable of organising the fluids? and although nutritive particles or aliment help to preserve life, they are incapable of accomplishing such an end until some wonderful change has been wrought upon them by life. Besides, the very idea of anything arranging itself, of producing a state in itself which it never before represented, and which, in fact, is unnatural to it, is truly absurd. Added to this, every organ appears to be regulated by different laws, and there are no two organs which differ in composition that are instrumental in effecting the same end, and whatever laws are absolutely exercised over matter, I consider to be independent of that matter. As the fluids which are destined for fabrication

circulate, a peculiar influence is no doubt transmitted to them by life, the organs or vessels being required at the same time to assist in their preparation and deposition. The matter which is received into the stomach for digestion is assimilated and prepared by life, but many fluids are poured into this organ for the purpose of assisting the process and adding extra qualities to the digesting mass; yet the peculiar influence belonging to their several fluids is not occasioned by any muscular action of the stomach, or any combination of fluids or mode of circulation; and if blood be a fluid retaining life, it may be said, that the whole influence exercised in converting it into fabric is not *entirely* owing to those vital powers which belong particularly to the organs from whence the new fabrication, or supply, or organisation arises, but also to that vital influence which had been imparted to the blood previously. It is generally believed that this fluid possesses life, but whether every fluid is possessed of it, is a question not easily solved.

It now appears that animal function, as it is termed, is an act of life; and as the functions are very numerous, and every action must arise from power or a producing capacity, and every power must inherently exist with some principle or substance, and as different effects cannot result from the same action, and one power is incapable of producing several actions, it would appear that as there are innumerable different functions carried on in the system, that different powers are concerned in performing different functions and producing different conformations, which implies, that while life is organising and animating the body, it possesses as many powers as there are functions to be performed and ends to be accomplished; still, while life is capacitated for being in constant motion, it does not consist of motion, as some believe, but all functions which are effects and the results of a principle which of necessity is independent of them, may still be causes; and if they should cease to exist, the cause is not to be found in them but in that of which they are supposed to be effects; yet this conclusion no way militates against its independence of function, and although the organs are different in shape and composition, it does not follow that the properties of life are different in different organs, nor can we suppose the difference in organs is owing either to a diminished or increased state or degree of life,

nor to a different principle or kind of life; if life admit of modification, it must consist of parts, and then be material; and if there be a different principle or kind of life in each organ, there must be as many different lives in the body as there are organs. Life, as being immaterial, is a simple, uncompounded, and indivisible essence, and therefore it must be the same in every atom of the body. Vital powers are to life what bulk, figure, extension, and solidity are to matter; and as it is not the province of any essential properties to act (at least according to the views of our limited understanding), I conceive that whatever there is in spirit capable of acting, may be considered as active capacities or powers; and I do not believe it is at all difficult to conceive, that the difference in organisation and the different functions, proceed from a variety of these powers. It is not possible, from the nature of life, that one organ should possess powers which another does not, because it is certain that life, or all its properties, powers, and every conceivable thing belonging to it, must pervade every part alike; yet it does not follow that the same powers are to act in every part, or that some are not destined to act in one part and some in another, without having such powers as may be inactive positively abstracted. Of course this is nothing more than conjecture; but without knowing the nature of spirit, and the laws of connexion between life and body, it is not an easy matter to render the subject more intelligible; we will conclude, at all events, that the same power does not fabricate every organ and perform every function; that if the results are different, if digestion, fabrication, and secretion are different processes, that the cause of each must be different. We can ascertain the distinction between the several vessels of the body, and be confident that, through their instrumentality vital actions are exercised and different effects wrought; and although the mere form and composition of the organs are not the cause, still each distinct process requires a peculiar conformation, even independently of any vital power.

We need not inquire whether the vital influence imparted to any solid or fluid be active or passive; but it is evident, that although we see an organ acting, we know no more how this influence is communicated, or how life applies itself to structure in order to produce

action, than the most unconscious being ; and as all spiritual essences are beyond the comprehension of man, we cannot possibly tell what they are, and what they are not, capable of ; it cannot, therefore, be absolutely disproved, that life acts in numberless ways, and possesses many capacities. By admitting that different capacities exist, and that each instrument possesses an individual economy, we are enabled to discover many new and interesting particulars.

For the action of one organ the assistance of a great many others is required ; that is, since we cannot understand that a function ever existed without an association of organs, we must of necessity suppose such an association to be necessary for every function ; but the great question, and one that has never yet been comprehended, is,—What is the state of life when an organ is operating, and a peculiar combination produced ? We believe that it possesses powers, properties, and laws, and this information we gain from our conceiving it impossible for any thing to exist without such qualities. There is not an action nor an event which transpires in the human frame, but is capable of bearing evidence to the existence of a cause which has no relation in point of real being, and is not subservient to, nor produced by, the organ—the medium of action—the instrument through which the events are made known to us. However, we must admit the laws of connexion, or that incomprehensible something in spirit, which, although infinitely opposed in nature to the body, allows itself to exist with the gross particles of matter, act with them, and change them, to be that which every philosopher would most willingly understand : and no doubt we are made acquainted with many facts concerning it, by attentively observing certain visible signs—the great uniformity of structure—the delicacy and unalterable shape and composition of every organ—and the connexion subsisting between the several operations.

No one vital power could operate without the interference of the other powers, at least, a concurrence of the powers is necessary to the existence of the changes which take place ; so, without circulation there would be no exhalation, nor any other vital process ; and without secretion, the process of digestion would cease. The motion of the heart is necessary

to the functions carried on in the most extreme parts ; and the series of actions, while mutually influenced by one another, are the results of indirect as well as direct causes ; and such is the nature of life—of each power—of each cause, that it is destined to furnish some fixed result, and to make that result co-operate with other causes and their results ; and as the ends to be accomplished are very numerous, there must accordingly be equally numerous causes, each of which, while producing some certain effect, and assisting in the production of other effects derived from different causes, must either be immaterial, or the result of immaterial influence.

We may conclude by saying, that the epithet *life* is used to denote the cause of that uniform assemblage of organs and functions which is found in the human economy,—to denote that which distinguishes what is inert and inanimate from what is not ;—that which develops the body in forms too apt, too complex and refined to resemble any thing where it does not exist ; and when we reflect on the apparently unlimited powers and nature of life, and turn our thoughts to the Being who instituted the laws of nature, and endowed life with such powers, we must acknowledge the wisdom of that Being, and be conscious that our souls are more aspiring than gifted with the fruits of real knowledge. How a principle which has no parts should operate, or how a cause which is invisible and without parts should make its effects visible, is a mystery which every inquiring mind would solve, if possible, and which we can reconcile only by supposing, that in such a case nature and Divine Wisdom go hand in hand. Unlike the objects of sense, which experience neither pleasure nor pain, which are not vital spirits nor intellectual beings, but belong to the external universe, and constitute what we call visible or material nature, it is not only immaterial, but distinct from both mind and soul, which, like every thing spiritual, may leave the world without taking any part with them. Life, while remaining in union with the body, is most active and efficient ; it adheres to certain laws, adapts itself to various circumstances, applies powers suited to all forms of structure ; its province is great, and its capacities no less numerous than powerful. Observe its effects ; the construction of a mountain is acknowledged to be wonderful, but

what is it compared to the fabric—the construction of the animal body, which this principle has formed, to the surprise and delight of mankind. Think of the minuteness, perfection, and aptness of every organ,—of the uniformity of the whole body, and of all the organs, some of which are almost imperceptible, and all undergoing perpetual changes! and at that instant will our thoughts be directed to a cause far above the qualities of gross matter. We cannot philosophise upon life without noticing the result of function, or the progress through the many stages organic matter passes in its development, and the influence exerted over it by the powers of life; and so infatuating is the subject, that we sometimes desire to comprehend not only vital nature, but the infinite attributes of the Deity. It is impossible that any unprejudiced mind can reflect upon and acknowledge the diversities displayed by life, which must have a cause, without reflecting on and acknowledging the exceeding wisdom and power of that cause—the Being who “broods over the face of the deep, and breathes into man the breath of life.” While endeavouring to learn by what means the workmanship of the body is effected, and feeling our inability to comprehend it, can we disown, as the atheist does, the existence of a Being more primary, more efficient, and more infinite than life? Can life, on which human ingenuity cannot work, and which the soul cannot comprehend, be supposed to have such an existence, and be possessed of such powers independently of a creator, a Being more capable than itself? Certainly not. The world in its stupendous whole, and every thing except one, must be an effect, and that which is not an effect can be no other than He, whom the Christian worships and adores as the God of Nature, the only Being omnipotent.

CASES OF CÆSAREAN OPERATION.

BY JAMES BARLOW, SURGEON, BLACKBURN.

It is to be regretted, that although the records of surgery furnish a greater number of successful cases than those of a less fortunate nature; still it not unfrequently happens, that adventitious circumstances occur in surgical operations, which, when con-

cealed from public notice, become of no avail to science, but if allowed publicity, might prove eminently beneficial to the advancement of our art, and ultimately tend to the alleviation of human misery.

Governed by these considerations, that a faithful though unfortunate narrative would frequently prove most instructive to the practical surgeon, I have been induced to present the following case of Cæsarean operation for insertion in the *London Medical and Surgical Journal*.

Mary, the wife of Edmund Forrest, resided about three miles from Blackburn, was a poor decrepit woman in the thirty-fifth year of her age, who had suffered greatly from an accession of rheumatic pains of the loins for a series of years, which eventually produced a state of malacosteon and deformity, which rendered her unable to walk without support for the last three years of her existence. She also laboured under anasarca, with an ulceration of the lower extremities, troublesome cough, and difficulty of breathing.

Unfortunately in this situation she became pregnant of her fifth child, and when at the expiration of the period of utero-gestation, she was seized with labour pains, and Mr. Cocker, pupil to Mr. Pickop, surgeon of this town, was called to attend her on Monday, the 21st of August, 1826. Mr. Cocker stayed with her all night, and occasionally made the necessary examinations to ascertain the progress of labour and position of the fœtus, but found to his surprise the apertures of the pelvis so unusually distorted, that he concluded she could not be delivered in the ordinary way, though the pains were rather strong and frequent.

The following morning (Tuesday), Mr. Pickop visited her; at this period labour had made little progress, the liquor amnii had not escaped, though the pains were more powerful than before, and the woman's sufferings greatly aggravated by a distressed breathing, a quick and irregular pulse,

scarcely numerable, together with obvious constitutional debility.

On a strict examination per vaginam, the distortion of the apertures of the pelvis appeared to Mr. Pickop so contracted, that he was unable to attain a knowledge either of the state of the os uteri or presenting part of the fœtus. An aperient clyster was administered, and Mr. Pickop left her, with strict injunctions to be sent for on the advance of labour; in the course of a few hours he was recalled, and on his way solicited my assistance on the case; we set out together, and arrived at the patient's dwelling about nine o'clock the same evening, and found her laid on a bed, with her head and shoulders supported by her husband, gasping for breath, and apparently in a dying state. On seeing me she earnestly begged that I would release her from her misery, as she could not live long in her present state.

Without delay I made the necessary examination, and soon discovered the deformity of the pelvis and impediments to delivery in the natural way to be as had been stated to me previously by Mr. Pickop; and though I took much pains to ascertain the situation and state of the os uteri, as well as position of the fœtus, by making pressure on the abdominal region with one hand, while the index finger of the other was employed in the vagina, yet I could not, even by this manœuvre, attain my object, owing to the evident distortion of the pelvic apertures and pendulous state of the abdomen, yet during this research I was enabled to predict the living state of the fœtus by the motion conveyed to the hand through the medium of the uterine and abdominal parietes. The woman's pulse was irregular, and too quick to be enumerated; her breathing oppressed and interrupted, attended with rattling of the throat; and countenance exhibiting a ghastly appearance, all of which symptoms indicated approaching dissolution, and from Mr. Pickop's account were greatly aggravated since he left her in the morning.

In this perilous state a question arose, whether to have immediate recourse to the Cæsarean section, or abandon any further interference in the case. But, on being urged to the operation by the supplications of the woman and her attendants, and knowing the fœtus to be alive, I more readily yielded to their entreaties, believing it to be a professional duty rather than sacrifice the child by unnecessary delay and timidity.

The management of the case having been resigned to me, I had the woman removed from the bed and laid on her back upon a table, with her head and shoulders slightly raised with pillows, to assist her breathing, and while the requisite dressings, &c., were preparing, Mr. Pickop introduced the catheter into the bladder and evacuated its contents.

I commenced the operation about two inches above and a little to the left of the umbilicus, by making an incision in a longitudinal direction to the extent of six and a half inches, and parallel with the fibres of the linea alba, through the distended parietes of the abdomen, which were very thin. The peritoneum being laid bare, a small opening was next made therein, which admitted the point of the finger, and served as a director to the probe-pointed bistoury, by which this membrane was divided upwards and downwards, to the full extent of that of the integuments. The uterus next arrested my attention, and was divided in the same way and to the corresponding extent with the other tunics, and its parietes were observed not to exceed in thickness the edge of a half-crown in any part of the incision.

A portion of the placenta was found adhering to this part of the organ, and its membranes being ruptured with the fingers, the liquor amnii was allowed to escape by the abdominal wound rather than become diffused among the intestines. An incision was then made through the vascular substance of the placenta, which exposed the left shoulder of a female

infant to view, with its head situated at the fundus uteri; the child was extracted alive, and on the funis umbilicus being tied and divided, it was resigned to the care of a female attendant.

The placenta and membranes were then detached from their connexions and extracted without difficulty, and the uterus contracted as speedily as is usual in ordinary deliveries, and the incision became nearly closed; consequently there was very little blood lost during the operation, except what escaped from the divided edges of the placenta whilst attached to the surface of the uterus.

This part of the operation occupied only a few minutes; but the joy produced on the occasion excited great agitation of the system, with laborious breathing, and a considerable portion of the bowels became forced through the abdominal wound, though every effort was exerted to retain them in their place.

During this interval the poor woman seemed almost exhausted, but having a little wine allowed her, the breathing and throbbing of the chest became more tranquil, which greatly aided our efforts in replacing the intestines *in situ*, on which she gratefully expressed her thanks at the event of the operation.

Mr. Pickop now supported the sides of the abdomen with the palms of his hands, and pressed the incised edges of the integument in contact, whilst I secured them by means of several sutures placed about an inch apart, over which were applied pledgets of dry lint and strips of adhesive plaster, and the whole surface was finally protected by a broad bandage passed a few times round the body so as to keep the abdomen and its contents steady, and the interrupted sutures from being too much extended.

Her pulse, which before the operation could not be distinctly counted, had now subsided to 108, with the breathing less laborious and mind more tranquil. Twenty-five drops of tinct. opii were given in a little wine,

after which we left her about eleven o'clock to the care of her sister, with strict injunctions to be kept quiet, and such regimen allowed as her condition required.

The following morning (Wednesday) Mr. Pickop visited her, and was informed she had passed an easy night, and slept at intervals. The bowels being constipated an aperient enema was administered, but without much effect. She had passed urine freely.

Mr. Cocker saw her in the evening; pulse regular, and about 110, and she was free from pain or fever. On Thursday morning I called upon her, and she said she had got some refreshing sleep during the night, and appeared cheerful and communicative.

The temperature of the skin was not increased, and there was a slight moisture; pulse 110, firm and regular; tongue moist and perfectly free from fur, she nevertheless complained of thirst and sickness, with occasional vomiting. The bowels not having acted since the operation, the clyster was repeated, but without effect. I prescribed a saline mixture, a dose of which to be taken at short intervals in the act of effervescence, and eight grains of calomel made into pills with two drops of croton oil, which soon produced several copious evacuations. I now removed the superficial dressings from the wound, together with each other strip of adhesive plaster so as to inspect the healing process, and was pleased to find, that the incision of the integuments was completely united, and the dressings dry and scarcely stained with discharge from the part.

The abdomen felt on pressure rather tense, but did not excite pain; the lochial discharge was uninterrupted, and appeared in every respect as is usual after natural parturition.

On Friday morning she was visited by Mr. Cocker, who was informed that she had passed a quiet night, her pulse 115 in the minute; tongue moist and clean; breathing more laborious than before; urine evacuated naturally, and in sufficient quantity.

In the evening Mr. Pickop saw her, when she was evidently much changed, with pulse 160 in the minute; great tremor and distressed breathing; thus she passed a restless night, and died about eight o'clock the following morning (Saturday), being rather more than three whole days subsequent to the operation. It is now nearly seven years since the operation was performed, and the child is at present enjoying a good state of health.

It is necessary to remark that this case of Cæsarean section excited among the surgeons of our dispensary a groundless suspicion of its having been unnecessarily performed, in consequence of which the body was clandestinely disinterred, and the following is a correct copy of the report taken down in writing, by a medical pupil during the dissection, and the dimensions of the pelvis (which is now in my possession) will convince any one who reflects on the space allowed for the passage of the fœtus, that the operation was in this instance imperatively called for. The deformity of the pelvis in the instance previously related, it may be necessary to state, was produced by malacosteon.

Post-mortem examination of the body five days after death.—The abdomen was not unusually distended, and the muscles had apparently regained their natural form. From the violence used in removing the body from the grave to the place of dissection, the wound in the integuments of the abdomen was slightly separated, and there was every appearance of its edges having been recently lacerated.

On removing the sutures and extending the incision, the intestines and uterus were exposed, upon neither of which was there the slightest mark of inflammation.

The peritoneum was not at all inflamed, but on the contrary was very pale, as were also the intestines.

The uterus was remarkably small and contracted; the incision in this organ was scarcely two inches in extent, its edges three quarters of an

inch in thickness, were in perfect apposition, and had so firmly united that it required considerable force to tear them asunder. There was, perhaps, an ounce of coagulated blood effused upon that part of the peritoneum which was in contact with the wound in the uterus, it was evidently undergoing the process of absorption.

The liver was very small, and the gall bladder was greatly distended with about thirty stones of various sizes.

It is worthy of remark, from the appearances of the uterus, as stated on dissection, that in all probability this woman would have recovered from the operation had she been afflicted with no other disease than malacosteon.

Diameters of the superior apertures of the pelvis.—The transverse diameter measures $4\frac{1}{2}$ inches, taken from one sacro-iliac symphysis to the other.

The distance from the right acetabulum to the projecting lumbar vertebra, is only half an inch.

The distance on the opposite side, one inch and a quarter.

The largest circle that can be formed in any part of the superior aperture does not exceed one inch and a half.

The antero-posterior, or sacro-pubic diameter of the brim is two inches.

The coccy-pubic, or long diameter of the outlet is two inches and a half.

The bis-ischiatic, or short diameter from one tuberosity of the ischium to the other, is two inches.

[Mr. Barlow when in town during the autumn did us the favour of showing us the pelvis referred to in the preceding remarks; and the admeasurements are exactly as he has stated. The case reflects great credit upon him as a judicious operator, and as an obstetrician of great experience and judgment. Few surgeons would venture to operate under such untoward circumstances, but Mr. Barlow has the great gratification of frequently seeing the child whose life he so courageously preserved. In conversing with him on his successful and celebrated case of the Cæsarean section,

he mentioned some particulars respecting it, which he did not publish, and as we consider these of the greatest importance to abdominal surgery, we shall republish the original case, and include the new matter in brackets.—Eds.]

“Jane Foster, of the village of Blackrod, was in the 40th year of her age, of a robust constitution, and mother of several living children.

“She had the misfortune, on returning from Wigan market, to fall from a loaded cart, the wheel of which passed over her pelvis as she lay on her back. The injury she sustained from this accident made confinement to her bed necessary, for about six weeks. She was attended on this occasion by the late Mr. White, of Manchester, Mr. Hawarden, of Wigan, and some others.

“From enquiry of Mr. Hawarden, I learned that one of the ossa ilei was fractured, and much injury done to the whole pelvis, particularly to the ossa pubis. This information was confirmed to me afterwards by Mr. White, in a conversation I had with him on the subject. The woman being then in great misery from the accident, was very adverse to an accurate examination, yet the above statement seems highly probable, both from an irregularity at the part, and from the elevation of the head of the thigh-bone, on the left side. This produced a shortening of the limb, and of course a limping.

“Soon after her recovery from this injury she became pregnant, and on Friday, Nov. 22nd, 1793, she was seized with labour pains, being then at the full period of utero-gestation.

“The midwife, who attended her in her former labours, was sent for on this occasion, but having waited with her several days, without the least prospect of delivery, she thought it advisable to have more assistance, especially as the waters were discharged on the second day of the labour, and no part of the child could be ascertained to present within reach. On Tuesday the 26th, I was desired to meet Mr. Hawarden, of Wigan, upon a consultation on this case, but, arriving a little before him, I examined the parts per vaginam, and was extremely surprised to find that I could barely pass my finger between the ossa pubis and the last lumbar vertebra, so great was the nar-

rowness at the brim. Besides this, the outlet was so much contracted, that it was with some difficulty I could introduce three fingers at that part. [The nurse denied that the patient had received any injury; she assured Mr. Barlow that the woman had children before without any operation, and some were in the apartment. He was greatly surprised at this statement, and, on retiring to an adjoining apartment, he overheard the nurse observe, that he ought to be told the truth, or he would leave as the two practitioners, who had preceded him, had done.]

“After asking some questions, I was informed of the accident. This information induced me to repeat my examination with more exactness, in order the better to ascertain the precise dimensions. Having introduced my finger again, I perceived a very evident depression of the ossa pubis, with a protuberance in a direction somewhat more towards the hollow of the sacrum, than in an exact line with the last lumbar vertebra. From this I was led to suspect, that there had been besides the fracture, a separation at the symphysis pubis, and that the protuberance just mentioned was the consequence of a deposit of bony matter at the separated part: and some idea may be formed of its quantity, from knowing that it projected to within half an inch of the os sacrum. With some difficulty I carried up my finger sufficiently high to judge concerning the degree of dilatation of the os uteri, which appeared to be considerable, as far as I could judge from feeling its anterior edge, which was thin and flabby; but no part of the child was within reach.

“Her pains had left her the night before; her anxiety was very great, her pulse full, and respiration difficult. This last symptom was moderated by the loss of ten ounces of blood from the arm.

“On conversing with Mr. Hawarden, he concurred with me concerning the nature of the case, and the impossibility of bringing the child away by the natural passage. Some little conversation passed on the propriety of a division at the symphysis pubis, but it appeared to us both, that the narrowness at the brim was too considerable to allow much advantage from such an operation, therefore that project was soon abandoned. The only alternative was the Cæsarean Operation; but the well known danger of this induced Mr.

Hawarden to decline taking any part in it, and he immediately returned home.

"Convinced, therefore, of the impossibility of effecting delivery by any other means, it was proposed to her attendants, but was not then assented to. Indeed the idea seemed so dreadful that I did not urge it much, especially when I recollected, that of the nine or ten instances then on record, in which that operation had been performed in this country, not one had furnished a voucher for its success. In this forlorn and dangerous situation she was left to the care of the midwife, and desired to make up her mind as soon as possible concerning the operation.

"On the morning following (Wednesday 27th), [5th day of labour] I was again sent for, and found her lingering in the same situation.

Note.—[30th. Sitting up eating cockles with her children, contrary to Mr. B's directions.]

"She consented to the operation without the least hesitation. I immediately called in an assistant in the operation, Mr. Hawarden, a practitioner in the village (Blackrod), and brother of Mr. Hawarden, of Wigan, before mentioned.

"The patient being taken out of bed, and placed upon a table, lying on her back, with her head raised by pillows, I began by making a longitudinal incision, five inches and a half in length, as high as the navel, parallel to the *linea alba*, and about two inches to the left of that line. [Transverse incisions are better, as healing sooner.]

"The integuments and the left rectus muscle being cut through, a small opening was made through the peritoneum at the upper part; and by means of a probe-pointed bistoury, this membrane was dilated to the same extent as the external parts*. The uterus was now exposed to view, and an incision of the same length was continued through it. The child presented with its breech, and was

extracted through the artificial opening, but unfortunately was dead, yet did not show any material signs of putrefaction. The placenta and membranes were then extracted with the greatest ease through the wound. The uterus was very thin, scarcely exceeding that of the peritoneum, and equally so through the whole extent of the incision. No attempt was made to examine the pelvis from the abdominal wound. The hands of a female assistant were applied on each side of the abdomen, to prevent the admission of external air, and to press out any blood that might be diffused among the intestines, after which the sides of the wound were brought together and secured by seven sutures, over which slips of adhesive plaster were applied, and the dressing completed by a few turns of a flannel bandage round the body.

"The peritoneum was not included in the sutures, and no part of the viscera protruded during the operation, neither were there any blood-vessels divided, which required to be secured by ligature. It was a fortunate circumstance that no hæmorrhage followed the extraction of the placenta, as was to be apprehended from an atonic condition of the uterus, the effect of long distension. The womb contracted properly, the lochia were about the usual quantity, and continued as in other cases. The poor woman scarcely complained during the operation, so great was her fortitude. Soon after she was put into bed, she slept without taking any medicine for that purpose, and passed a good night. On the 29th she complained of a fulness about the region of the stomach, with an inclination to vomit, and on laying my hand on the abdomen, a degree of tension was distinguishable. Her tongue had a whitish appearance, and her pulse was about 120. A laxative clyster was administered with the desired effect, and the painful tension of the abdomen yielded to the stimulating effects of a blistering plaster. In short, all the symptoms which had before indicated irritation, now suffered a very obvious remission. Four days having elapsed since the operation, it was thought eligible to remove every other suture; on the sixth the remaining ones were taken away, and the wound appeared perfectly healed [by the first intention].

"Though she had been a nurse to her other children, she experienced no uneasiness in her breasts on the present occasion. Her health continued in an improving condition until De

* It may be requisite to state, that at the commencement of the operation Mr. Hawarden was suddenly seized with a violent fit of syncope, which wholly incapacitated him from attending to the steps of the operation, and having no other professional person present, I was obliged to be assisted by a female attendant.

ember 4th, when it received some interruption for a few days from a diarrhoea, but which was checked by an astringent mixture. On the 10th she ventured out of bed, on the 17th she began to attend to her domestic employment, [and at the end of a fortnight she went to her church], from which time to the present, 1822, (an interval of 28 years) she has had a good state of health, menstruated with regularity to the usual period of life, but never has been pregnant. [This woman died about the year 1828.]

**MEDICAL REFORM.—WESTMINSTER
MEDICAL SOCIETY.**

“Viresque acquirit eundo.”

IN the stage at which Medical Reform has at length arrived, it may be allowed us to pause for a moment, and indulge with honest satisfaction in a passing retrospect of the principles, which we have uniformly advocated touching this important measure. We can trace our labours in the cause to a time, when nothing but disunion and apathy pervaded the profession. The demon of corruption was then too firmly seated on his throne to render it prudent or safe for any private subject, except such hardy rebels as ourselves, to renounce his allegiance and unfurl the banner of reform. At last, however, amidst the general revolutions which characterise the age, our *treason* is on the point of becoming *successful*. Our partisans have increased to an alarming extent. The discontent is no longer confined to secret whisperings. Public manifestoes are issued against the usurped authorities; and what is worst, the boldest language of the original malcontents is repeated, and their principles asserted.

We must confess we have felt the greatest satisfaction in finding the senti-

ments expressed at the last meeting of the Westminster Medical Society, so perfectly in unison with all we have advanced at other times, and under other circumstances, in our character as journalists. Such public approbation of our principles is the *honorarium quiddam*, to which we look forward as the reward of our exertions in the public cause. We are not levellers, on the one hand, who think every distinction in society an infringement on the rights of man, and every ancient institution a mark for their mischievous sport; nor are we, on the other hand, blindly attached to every thing prescriptive, without regard to its adaptation to the altered state of society. In our projects for reform, we have endeavoured to square our conduct by that rule which Bacon pronounces good. “It is good,” says he, “not to try experiments, except the necessity be urgent or the utility evident; and well to beware that it be the reformation that draweth on the change and not the desire of change that pretendeth the reformation.”

The object of the last meeting of the Westminster Medical Society attracted, as might be expected, a very full attendance of the medical profession. Dr. Somerville’s speech in opening the discussion, will be read with great interest. It contains a succinct and lucid statement of the grosser abuses of the system, and, what seemed very superfluous, a kind of defence or apology, for the conduct of the independent members of the profession, in meeting in the Society to canvass their grievances. The persons, whose wrath he was deprecating, will never forget his unpardonable offence against their supremacy. They have sinned too deeply to forgive. With respect to the physicians, their narrow exclusive test of fitness for admission to their fellowship,—its total irrelevance to professional talent,—its

monstrous hardships upon the great body of medical practitioners,—its gross absurdity, when it turns out to be based, after all, upon religious professions—and these notoriously insincere,—were very ably illustrated.

The College of Surgeons has rendered itself obnoxious to the liberal members of the profession, by the selfish policy of its governors. They are self-elected, self-perpetuated, and, in consequence, irresponsible. And, above all, they have merited the severest censure of the public, in their neglect of midwifery as a branch of education.

We can never sufficiently admire the happy issue of the Apothecaries' application to the Chancellor of the Exchequer, for a reduction of the duty on glass. Out of this simple trading transaction with His Majesty's revenue, of great importance no doubt to patients, arose that piece of legislation—the Act of 1815, which has bestowed upon a trading Company the sole regulation of medical education, and has operated to level the qualifications of medical practitioners to the *minimum* requisite to pass the Hall. A still greater evil is felt in the uncontrolled powers the Act gives, or is supposed to give, to chemists and druggists, to practise without education, the very art for which Apothecaries were originally incorporated.

After a summary of these abuses, and the further abuse of apprenticeships, Dr. S. briefly pointed out the remedy he proposed, in the institution of one Faculty of Medicine or College of Physicians and Surgeons, to preside over and regulate the medical profession in the United Kingdom; and concluded with a resolution, that the Society concurred in the general desire for a parliamentary inquiry. Mr. Costello, in seconding the motion, observed, he was convinced the

continental system would not be received in this country. We have, in a former number, given an abstract of the French law for the regulation of the medical profession; we have since received full accounts of the reforms meditated in that system, under the authority of M. Guizot. The subject is full of interest, and it is our intention to return to it in a short time, when we shall have an opportunity of examining its details at length, with reference to the reforms necessary in our own medical institutions. In the meantime, as the discussion of the resolutions which embody the proposed alterations is adjourned to the next meeting, we must reserve any remarks upon the plan for another occasion. The opinions expressed by Dr. Copland, who moved the second resolution, were the echo of certain observations contained in former number of this journal, which, at the time, gave great offence to certain practitioners, for no other cause, can we imagine, but that they were too well founded; need we say we allude to the indecent traffic in fire-boxes, matches, quack medicines, and such stuff, which is openly carried on by some, who presume to call themselves medical practitioners. It is with pleasure we had the concurrence of such an old reformer as Dr. C., whose labours in the cause we have the honour of continuing in our condemnation of such gross abuses. Nor can there be a more interesting subject to the respectability of the profession, than the practicability of checking the mean violations of medical ethics to which the worthy doctor alluded. After an able exposé by Dr. Jewel, of the conduct of both Colleges, in neglecting to provide the public with competent practitioners in midwifery, and some observations by Drs. Webster and Ryan, who moved and seconded the resolution against

the College of Physicians, the debate was adjourned to the next meeting of the Society.

We need scarcely add, that the discussion of the abuses of the medical corporations, and their unfitness for the present state of society, was conducted without a dissentient voice; all were unanimous in voting them nuisances. The more difficult task of reconstructing the ruined edifice remains still to be accomplished. Whatever be the general opinion of the Society on Dr. Somerville's plan, the proposal to petition parliament for a parliamentary committee, will, at all events, meet with general concurrence.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, November 23, 1833.

J. T. PETTIGREW, Esq., F.R.S. in the Chair.

Medical Reform.

DR. SOMERVILLE rose, pursuant to notice, to introduce the important subject of medical reform before the Society, and he felt satisfied that it would be coolly and impartially discussed. The profession was nearly unanimous in opinion, that the present condition of the faculty was debased and degraded. All admitted, except those implicated in existing abuses, that the medical corporations of the United Kingdom were totally unsuited to the present period. He was not one of those destructives, who would propose to pull down colleges; but he was a strong advocate for adapting them to the spirit of the times. It has been said, that this Society was not the place to discuss medical reform, and to this he was prepared to answer, that physicians, surgeons, or apothecaries were not allowed to state their grievances in the institutions to which they belonged, for, in fact, they had no connexion with them. He would prove the truth of this opinion, by a brief exposition of the abuses of each of the corporations in London. The College of Physicians had divided its members into fellows and licen-

tates, and established unjust distinctions, contrary to the original charter. The college by-laws excluded the ablest physicians from the fellowship, unless they were educated at Oxford or Cambridge, where there were bad medical schools. The Professor of Practice of Medicine in one of these Universities, resided at Worcester. In the course of time it has happened, that medical schools in both Universities have become very inferior to those in other parts of the United Kingdom, and in different parts of Europe. Is it not then unjust and preposterous, that no one can be elected a fellow, unless educated at either University, or at Trinity College, Dublin, while graduates of all other national and foreign Universities are ineligible, though having had superior advantages. This college would not admit Dr. William Hunter, or a host of the most scientific physicians, while empirics are allowed to slay his Majesty's lieges with impunity.

The College of Surgeons are not representatives of the surgeons of England; the Court of Examiners and Council are selected individuals, and the members at large are excluded from all place and interest in the management of the institution. The late justly celebrated Mr. Brookes was never elected to any office, and another anatomist was persecuted, until the profession advocated his cause, though he soon became a professor in the London University. With respect to the Society of Apothecaries, he had to observe, that in 1814, when a few of them waited on the Chancellor of the Exchequer, to request him to reduce the duty on glass, they had little idea of acquiring the sole regulation of medical education. The College of Physicians and Surgeons neglected the interests of the profession, in allowing the Society of Apothecaries to obtain more power than the legislature ever intended. He admitted that the Society had done much good, but had prosecuted general practitioners, and ruined them, while chemists and druggists are unnoticed. The system of apprenticeship is condemned on all sides; and no one dissents from the opinion, that chemists and druggists, who do not receive a medical education, should be restrained from compounding drugs, or practising medicine. If we look at the state of the profession in any part of Europe, we find the laws relating to it much better

for the protection of public health, than in our own country. There is one faculty of medicine for the management of all matters relating to the faculty. He saw no objection to the appointment of a Medical Council or Faculty, composed of all scientific physicians and surgeons. A rumour is afloat that a royal commission will be appointed, but who ever heard of the labours of the commission appointed for Scotland in 1826. A parliamentary committee would be preferable, as it would be impartial and independent of all corporations; and he felt satisfied, that the Society would unanimously resolve to petition both houses of parliament, for a redress of grievances. Dr. Somerville then proposed the first resolution, which will be found appended to this report.

Mr. Costello seconded the resolution, and said, that after an explanation given to him by Dr. Somerville, he was convinced that the continental system would not be received in this country.

Mr. Dermott was of opinion, that the *con-cours* was the only system for the correction of abuses.

Dr. Epps observed, that a royal commission would do little good; and had medical men done their duty, we should be long since independent, but they had not responded to the general feeling. The spirit of reform was now abroad, and could not be controlled by royal commissions. The country was overrun by quacks, regular as well as professional, and the College of Physicians neglected to correct this and all abuses. He did not belong to that body, because religious tests were required of those who were admitted as fellows; they should swear to the thirty-nine Articles a hundred times over, at Oxford, Cambridge, and Trinity College, Dublin, though, perhaps, some of them never read them, and few believed in them. Such tests were contrary to the spirit of the times, and must be abolished. The resolution was then put and carried unanimously.

Dr. Copland rose to propose the second resolution. He believed he was the oldest medical reformer at the meeting; he had commenced more than ten years ago, when he was Editor of the *Medical Repository* (the former series of this Journal), but few joined him, and all fell off in a short time. We are governed by laws, in this country, which are not to be

found in any other part of the world, and which degrade us in the eyes of the public. Quacks are patronised by government—they are never punished; but if a medical practitioner commit an accidental error, vengeance awaits him. If the profession were regulated in a proper manner, none of its members dare disgrace himself by selling quack medicines; medical ethics would be enforced; and no physician dare attempt to oust the practitioner who called him into consultation.

Dr. Jewel seconded the resolution, and observed, that, according to the by-laws, no Fellow of the College of Physicians was allowed to enter a lying-in chamber. Dr. Hunter was ineligible, as well as all who practised midwifery. A president of the College of Surgeons published letters in the newspapers against those who practised midwifery, and was suspected to be the author of an abominable pamphlet, which was a disgrace to any member of the profession. In this country any one might practise midwifery; and those engaged in that branch saw daily examples of mischief inflicted by ignorant persons. In all parts of Europe, those who practised this branch, whether male or female, were obliged to receive a proper education; but the medical corporations of England grossly neglected their duty to the public and to the profession, by allowing ignorant persons to undertake this responsible and difficult branch of practice.

Dr. Webster rose to propose the third resolution. He was not one of those who would pull down existing institutions, but he would have them thoroughly reformed for the benefit of the profession and public. He condemned the religious test of the College of Physicians, as physicians of the highest talents were to be found among catholics, quakers, and other persuasions. The distinctions between Fellows and Licentiates was degrading and unjust, and could not be continued.

Dr. Ryan seconded the resolution, and said that as his opinions on medical reform were so well known to the medical world, he should not obtrude them on the meeting. He was a radical, but not an ultra radical reformer. He was not a leveller; but would contend that the present state of the profession was so degrading, that it must be thoroughly reformed. The conduct of the

College of Physicians was most degrading and insulting to its members or licentiates. These, in collegiate phraseology, were designated *alieni homines, minus docti*, though they were the main, the chief supporters of the medical literature of the country. Nevertheless, they dare not enter their own college, inspect the library or museum, without a special leave of the President and Fellows. There were Licentiates now present who had done more for the fame of British medical literature, than all the Fellows together. The name of Mason Good was not on the roll of Fellows, neither were those of Jenner, Hunter, &c. The College Examiners were often junior to the candidate, and their supercilious behaviour was the most uncourteous imaginable. Some of these Examiners were not known five yards from the College, and they, forsooth, were to ascertain the knowledge and experience of their seniors by many years, who could actually teach them the practice of medicine. He did not allude to the present Examiners, he really took so little interest in the College affairs, that he did not know who they were. Had the College admitted those who had done most for science, the museum and library would be augmented, jealousies would cease, and physicians would be infinitely more respected than they are at present.

Dr. Johnson then moved an adjournment, and Dr. Somerville was requested to read the remainder of the resolutions, which are as follows.

Moved by Dr. Somerville, seconded by Mr. Costello, and unanimously carried.

- I. That this Society participate in the feelings which so generally pervade the members of the Medical Profession, as to the necessity of a Parliamentary inquiry into the state of the Medical Profession in these kingdoms, with the view to its being placed on a footing more suited to the advanced state of medical science, as well as more consonant to the liberal spirit of the present age.

Moved by Dr. Copland, seconded by Dr. Epps.

- II. That the grievances at present so generally complained of by the members of the Medical Profession, appear to the Society in a great measure to arise from

the existing constitution, whether by charters, statutes, or by-laws, of some of the Medical Incorporations, to which the duty of regulating the Profession in this country has been intrusted.

Moved by Dr. Webster, seconded by Dr. Ryan.

- III. That the charter of the Royal College of Physicians of London, having been granted prior to the union with Scotland and Ireland, and at a period when the practice of medicine was in many of its essential features different from that of the present day, and its jurisdiction being virtually limited to physicians practising within seven miles of London, is inadequate to the important objects for which the charter was framed, and the by-laws of the College establishing an arbitrary distinction of practising physicians into two classes or grades, has proved, and, if permitted to exist, will continue to be, a source of jealousy, when the interests of the public require the utmost cordiality and harmony.

The following resolutions were read, and are to be discussed at the next meeting of the Society.

- IV. That the privileges conferred by the charter of the Royal College of Surgeons, limiting the number of members of the council to twenty-one, and giving to these individuals the power of appointing others, of their own number, whose appointments are to continue for life, and to whom is intrusted the examination of candidates for the diploma of the College, and by whom the regulations relative to their education are framed, is highly objectionable, and subjects the character of the council to the charges of exclusion, self-election, self-perpetuation, and irresponsibility.

- V. That the act of the legislature by which the exclusive privilege of licensing the General Medical Practitioners of England and Wales, under the designation of Apothecaries, is committed to a trading company, is derogatory to the character of the Profession, and injurious to the interests of the public.

- VI. That the exemption of Chemists and Druggists from all controul, as permitted by the act of 1815, is prejudicial to the

community. That it is highly expedient that all Chemists and Druggists should undergo a proper course of education and examination and be duly licensed for the dispensing of medicines.

VII. That any person assuming the title or designation of a medical practitioner, or acting as such without being duly licensed, should be subject to penalties, on information before the ordinary law tribunals.

VIII. That in the opinion of this Society, the evils now complained of will be remedied most effectually by the constitution of one faculty, or academy of medicine, which, under the direction of the legislature, shall preside over and regulate the education and practice of the medical profession throughout the United Kingdom.

IX. That the Committee of the Society be instructed to prepare petitions to the legislature, embodying the principles of the preceding resolutions, and that the prayer of the petition shall express the wish of the Society that a Committee of the House of Commons may be appointed, to inquire into the present state of the education and practice of the medical profession throughout the empire.

MEDICAL SOCIETY OF LONDON.

Monday, November 25, 1833.

WILLIAM KINGDON, Esq., the President, being absent, Mr. LEESE, V.P. took the Chair.

THE Secretary having read the minutes of the Society for the previous meeting, and these having produced no observations, it was proposed that a paper, written by Dr. Negri, *On the Efficacy of the Secale Cornutum in Hæmorrhages, and Leucorrhœa, and its Effects in Gonorrhœa*, which will be found in another page, should be read to the Society, and submitted to their discussion. The paper having been read ;

Dr. Shearman begged to be informed by Dr. Negri, in how many unsuccessful cases the remedy had been employed, as the doctor had only related the successful ones, and he (Dr. Shearman) thought that the substance in question could not be received as a remedy in such diseases, without being able to judge

in what cases it was of service, and in what it was improper.

Dr. Negri in reply, said, that he had tried it in three cases only, in which it did not prove successful ; these were cases of Hæmetemesis, which were relieved by other means.

Dr. Williams observed, that there was one case mentioned in the paper, in which there was disease of the spleen, and it was stated, that this disease disappeared with the one for which the remedy had been administered ; he wished to ask Dr. Negri if he considered that the ergot of rye had any influence over that organ.

Dr. Negri could not say whether the remedy in question exerted any influence over the spleen ; but, certainly, the protuberance observed on the left side disappeared with the original disease.

Mr. Proctor observed, that this was a most valuable paper, if the results mentioned in it could be relied on, as we were entirely at a loss in such cases, after having employed the customary remedies, what to do. He related a case of hæmatemesis, in which the patient was very weak from the loss of blood, and in which he had used turpentine with the greatest success, at the same time supporting the strength of the patient. He thought that the ergot of rye could not be used with safety where the disease depended on active hæmorrhage, especially of the lungs. He should feel obliged to Dr. Negri if he would inform the Society in what manner the *secale cornutum* acted, whether it acted as a stimulant, as this was a point of importance.

Dr. Negri thought he should be enabled to answer this question satisfactorily to the Society, when he read the second part of his paper, in which he should relate many cases of gonorrhœa treated successfully by the *secale cornutum*.

The President wished to be informed if Dr. Negri had found the use of the *secale cornutum* successful in the first stage of gonorrhœa.

Dr. N. replied that he had found it fail in several cases in the first stage of that disease, but it generally succeeded in arresting the discharge after the first stage.

Mr. Blenkaine thought it empirical practice to employ any remedy in the indiscriminate manner in which Dr. Negri appeared to have employed this. He thought that Dr. N. ought to have stated more fully in his paper,

in what cases the secale was of service, and in what cases it would prove prejudicial.

Dr. Whiting considered that, in the paper, which had been read to the Society, too great a stress had been laid on the effects of the secale cornutum, in the cases related by the writer, since other remedies had been employed before the use of that substance, and he thought that the success attributed to the ergot of rye, was only the good effects of the other remedies beginning to operate, when the secale cornutum was employed. He also agreed with Mr. Blenkairne, that a sufficient distinction had not been drawn between the cases in which this remedy would be of service, and those in which it failed.

Dr. Negri acknowledged that in all cases of hæmorrhage it did not succeed, as he had related in the introductory part of his paper. With respect to the remedy being employed together with other remedies, he certainly bled the patients where inflammation was present. If Dr. W. had paid attention to the first part of the paper, he would have seen that he (Dr. Negri) had neglected to use any other remedy whilst using the secale.

Dr. Whiting, in reply, stated, that, as other remedies had been employed, he still thought that to them might be attributed the good results related in these cases.

Mr. Proctor thought that Dr. Whiting attributed to the other remedies employed by Dr. Negri, an effect which did not belong to them, as they were only employed as preparatory to the use of the secale cornutum. In employing the acetate of lead, we always use some other remedies before this substance; but, the astringent effects of the acetate are never attributed to the remedies before employed.

A gentleman thought that this remedy ought only to be employed in passive hæmorrhages. He wished to know the *modus operandi* of the medicine. He himself had had occasion to administer it in a case where there was sickness, and, certainly, the sickness was arrested, which was attributed, by the patient, to this remedy. He thought, with several gentlemen who had spoken before, that it would have been better if it had been clearly stated in what cases this remedy acted with good effect, and in what it had a deleterious one. He should likewise wish to know the best form of administering it, and the proper dose in which it should be administered; as in some of the cases related in the paper, it was stated, that in some instances five grains were given, and in others twelve; he should therefore wish to know the precise dose.

Dr. Negri replied that he, in his own practice, never gave more than five or six grains at a time, but repeated the dose according to the urgency of the case. In some cases, he had given it every half hour, in others, every hour, and in others only three times a day.

As to the case in which twelve grains had been administered at a dose, he was indebted for that to another gentleman, and, consequently, could not answer for the manner of administration. He had employed the powder, as the mode of administering it, employed by Dr. S., who first made use of it in these cases.

The Society then adjourned.

MEDICO-BOTANICAL SOCIETY OF LONDON.

Tuesday, November 26th, 1833.

DR. RYAN in the Chair.

DR. SIGMOND read a paper on the *Matricaria Camomilla*, by Batha of Prague, and upon the real *Aconitum Napellus* of Stoerck, gathered in the Styrian mountains, which appears to be very different from the *Aconitum Napellus* of Willdenow.

A paper by Dr. Hancock on the superiority of honey produced according to Mr. Nutt's plan in the medicinal preparation of this substance was then read.

Dr. Tytler presented some specimens of the cotton-tree, and of plants which paralyse the scorpion, and prevent it from biting.

Professor Burnett delivered a most interesting and ingenious lecture on the different fungi. The thanks of the Society were returned to the learned Professor for his very valuable lecture; and it was announced that Dr. Ryan, Professor of *Materia Medica* to this society, would deliver a lecture on that subject on the ensuing meeting of the society, which takes place on Tuesday, December 10th.

APOTHECARIES' HALL.

VOL. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,**Session 1832—1833.*

LECTURE LXVI., DELIVERED MARCH 11, 1833.

GENTLEMEN,—Some diseases of the joints appear to begin in the synovial membrane, some in the cartilages, and others in the heads of the bones. In the last lecture, I was describing the affections of the synovial membrane, and especially that disease in which it is converted into a brown or light reddish-brown substance, marked by a number of whitish lines; a case frequently considered to be connected with scrofula, and regarded by Mr. Brodie as incurable, and nothing less than a total disorganisation of the texture affected. The disease, as I observed, is characterised by its slow indolent progress; there is, indeed, a great deal of swelling and stiffness of the joint; but the part is not painful, and has a soft elastic feel, which should not be mistaken for a fluctuation.

Ulceration of the cartilages, which I now proceed to describe, is more commonly noticed in the adult than the pulpy thickening of the synovial membrane, which has just been engaging your attention. It is not very easy to discriminate the incipient stage of ulceration of the cartilages from chronic thickening of the synovial membrane. In the early stage, there is generally no enlargement of the joint, but, after the disease has made some progress, the synovial membrane begins to be inflamed, and the case is then accompanied by swelling. Generally, however, for the first few weeks, there is little or no swelling; nor is any serious degree of pain experienced in the beginning of the complaint, unless the joint be exercised. Certain other forms of disease in joints are seen, in which there is constant pain, whether the limb be moved or not. At night, however, some pain usually accompanies the

present affection; and, after a time, as I have said, the synovial membrane becomes affected, and then, in addition to the ulceration of the cartilages, there is an effusion of fluid in the joint, which adds considerably to the swelling, and occasions a fluctuation. The latter circumstance may therefore be considered as sometimes constituting one of the symptoms of the disease. I should mention, that almost all the surgical diseases of the joints have a tendency to terminate in suppuration, and abscesses both within and without the synovial membrane, followed by fistulæ and sinuses, as well as caries of the bones; so that, unless you examine the disease in an early stage, you may not always be able to pronounce exactly in which texture it commenced. When abscesses form in the disease now under our consideration, the matter collects in the synovial membrane, and also ultimately in the cellular membrane on the outside of the joint, frequently spreading to a great extent under the thickened integuments, and at length making its way out by one or several fistulous ulcerations.

Here, gentlemen, is a specimen of disease of the knee-joint, attended with ulceration of the cartilages. You observe, that the synovial membrane is thickened and inflamed, and that coagulable lymph is effused; there seems also to be a kind of exfoliation of the cartilages,—an appearance as if some pieces of it were detached. It is rather difficult to say positively whether, in this case, the disease commenced in the cartilages or not. In this other specimen, extensive sinuses and fistulæ were formed, but they cannot be seen because the integuments have been taken away.

We must, I think, agree with Mr. Key, that inflammation of the synovial membrane is the most frequent cause of ulceration of the cartilages. Some of the cases, to which he refers, prove the existence of a long-continued synovial affection, before any ulceration of the cartilaginous surface could have taken place; for, in them, the cartilage was quite sound, with the exception of a slight loss of substance at the edge of the bone, where the synovial membrane was reflected from it, though the symptoms of diseased joint had existed for

many months, with pain over a large part of the synovial surface, and general swelling of the joint. According to Mr. Key's investigations, the inner part of the knee joint usually exhibits the most extensive ulceration, on account of the oblique bearing of the femur, and its unequal pressure on the inner part of the head of the tibia. Hence the inner semilunar cartilage is oftener destroyed than the outer one, and there is a corresponding destruction of the cartilage covering the inner condyle of the femur and inner part of the head of the tibia. The patella and extremity of the femur are stated by Mr. Key to be the parts, on which the ulcerative process can be best traced, on account of the disease being less advanced in them. In the former bone, the part which first commonly ulcerates, is the margin of the cartilage, where the synovial membrane is reflected from it. At this point, Mr. Key describes grooves of different depths as being formed, which cannot be always distinguished, until the thickened edge of the synovial membrane is raised. The ulcerated surface sometimes exhibits parallel vascular lines, verging towards the centre, and having their origin from the synovial membrane, which, if the vessels are well filled with fine injection, appears highly vascular and fringed, or villous, like a mucous membrane. This highly vascular fringe of membrane is a newly organised, and, as Mr. Key conceives, sometimes a superadded structure for the purpose of producing ulceration of the contiguous cartilage. When recently formed, some parts of it may be raised from the synovial membrane, but it adheres very slightly to that part of the cartilage where ulceration is going on: indeed, according to Mr. Key, this adhesion will not be perceived, unless the joint be opened with care. It seems, therefore, from these interesting researches, that the process, by which the ulceration of cartilage is here effected, is analogous to that by which the sequestrum of the cylindrical bones in necrosis takes place. The cartilage, indisposed to ulceration from the low degree of its organisation, is acted upon by the newly organised synovial surface, which is rendered highly vascular, and forms a groove in the edge of the cartilage, by means of its villous processes. We also learn from Mr. Key's investigations, that the granulations, which sometimes arise from the surface of the exposed bone, assist the membrane in the work of absorption. The formation of the vascular membrane frequently takes place without suppuration, as may be seen in strumous joints that have been the subject of chronic inflammation for years, without abscess having formed; and the inflammation is sometimes confined to one side of the joint.

The second mode, adverted to by Mr. Key, in which nature effects the ulceration of cartilage, without the agency of its own vessels, is exemplified, where suppuration follows acute inflammation, from a wound of the synovial membrane, which then undergoes a change,

enabling it to perform its new function. Its surface becomes highly vascular, and, in most parts, covered with a new deposit of adhesive matter, which is in many parts villous, or furnished with vascular fringed projections. In a joint, thus far advanced in disease, Mr. Key considers that the only mode of arresting the disorder, or of repairing the mischief, occasioned by inflammation, consists in the production of ankylosis. To this end, the removal of the cartilage is an essential step; and it would appear, that the office of removing it devolves on the inflamed synovial membrane. The absence of all action in the cartilage, and a total want of vascularity in those parts, where ulceration appears to be most active, were the circumstances which first led Mr. Key to look for some agent in the work of ulceration. The ulceration, as he explains, evidently begins on the surface of the cartilage, and not on that side next to the bone. It presents merely an eroded surface; there is no disorganisation of its texture in the parts where absorption is about to take place. The grooves are formed only in those parts of the cartilage, which happen to be opposed to the fringed and vascular synovial membrane. The removal of the cartilage, which is an impediment to ankylosis in many diseased conditions of joints, is what nature commonly aims at. In the most chronic form of strumous ulceration, the removal of the cartilage is accomplished, according to Mr. Key's researches, by the gradual development and organisation of the synovial membrane, where it is reflected from the edge of the cartilage. Where the process is required to be more rapid, a false membrane is effused from the edge of the synovial membrane, that gradually diffuses itself over the whole surface of the cartilage, and, by means of its increased vascularity, ulcerates the cartilage even to the bone, anastomosing often with the granulations of the exposed cancellous structure.

Another case, is where ulceration begins on the surface of cartilage attached to the bone. In examples of chronic disease in the cancellated structure, Mr. Key finds, that, when the cartilage begins to give way, vessels can be seen shooting towards it, and accumulating in sufficient number to form a vascular tissue, covering the attached surface of the cartilage. Afterwards, when the ulceration has proceeded through the cartilage, or nearly so, into the joint, the synovial membrane inflames, and the ulceration is then forwarded by a similar process, commencing at the edge of the cartilage, by means of the synovial membrane, and a newly developed vascular structure. In acute inflammation, attacking the spongy extremities of bones, the osseous substance is said by Mr. Key not to be softened, but to retain its firmness of texture, and exhibits no marks of disease, except at one part of the cancelli. Here a cavity is found, containing one or more portions of detached bone, surrounded with pus. This cavity communicates with the joint

by a fistulous opening of small size. The process of ulceration evidently begins on the outside of the joint, for the cartilage seems undermined, and its articular surface perfectly sound, while the synovial membrane itself is acutely inflamed, and its cavity has communications with one or more extensive collections of pus above and below the joint. These pathological researches, undertaken by Mr. Key, I have looked over with pleasure and instruction, and they seem to me to be well deserving of attention, as calculated to throw light on the difficult and obscure subject of the theory of ulceration in general. In Mr. Brodie's work, you will see that he was aware, many years ago, of some facts relative to this doctrine, which, however, he did not adopt.

The cartilage covering the articular surface of a bone being once destroyed, is reproduced with great difficulty; indeed, when cartilages are destroyed, and caries has attacked the subjacent bone, the disease must either terminate in ankylosis, which is, under such circumstances, the most favourable termination that can take place, or in a porcelainous or ivory-like deposit on the surface of the part from which the cartilage has been removed. I showed you a specimen of the formation of this curious deposit a few evenings ago. It principally occurs in the joints of old persons after mechanical injuries. The reproduction of cartilage is probably a very difficult operation, and generally, I may state, when the cartilages of a joint have been destroyed, there is hardly ever a cure except by ankylosis. In many instances, when the disease is in the knee, ankle, or elbow, hectic symptoms may begin even before suppuration commences, and especially when the disease is in the knee, though it rarely happens, that amputation is rendered necessary by the constitutional disturbance under such circumstances.

In the treatment of this form of disease of the joints, one obviously essential plan is, to keep them as quiet as possible; for every movement of the joint occasions a disturbance of the textures affected; and when the cartilages are ulcerated, friction of them, thus produced, must be particularly injurious. The treatment, then, consists in keeping the joint quiet, not only by making the patient observe the recumbent position, but also by the use of splints, or pasteboard, or by the method of strapping recommended by Mr. Scott, the principle of which is not altogether new; for I remember, that when I was a student at St. Bartholomew's Hospital, it was a common practice there to surround diseased joints with broad straps of adhesive plaster, which operated beneficially, no doubt, very much by maintaining the part strictly motionless. Another indication is, to endeavour to stop the morbid process, which, through the agency of the synovial membrane, and the new vascular substance developed from it, is occasioning the ulceration of the cartilage. For this purpose, experience has not furnished us with

any means more effectual than counter-irritation,—counter-irritation by means of blisters, issues, moxa, or antimonial ointment. However, this observation is to be received with some degree of limitation; for you will find in this, as well as in other diseases of the joints, that when you are first called in, there is often acute inflammation present, the part being painful and hotter than usual, from not having been kept quiet. Under these circumstances, it will be proper to employ common antiphlogistic means, before you have recourse to counter-irritation. On the Continent, and also in the surgical schools at Edinburgh, the cautery is sometimes recommended as a means of producing counter-irritation in the treatment of diseased joints; but in England surgeons rarely or never resort to it. Here we dislike heated irons as implements of surgery, which may be looked upon, perhaps, as mere prejudice, because no doubt is entertained of their frequent efficacy. That the cautery is a powerful means of relieving various diseases of the joints, I believe, is generally well known and acknowledged. It is what the French term an *heroic* remedy. After the morbid action has been in some degree stopped, you may then try other plans, such as pumping cold or warm water on the part from a height, as practised at some of the watering places. If the disease be arrested in time, the cure may take place without any material loss of cartilage, or consequent ankylosis, and after you have put a period to the disease, if there should still remain some uneasiness and weakness in the joint, you may try pumping water on the part from a height, *douches*, as they are called, or shampooing, or mere friction with the hand or with hair-powder. Ankylosis, however, is the common termination of this disease, and with this view it is that nature takes away the cartilage. Here is a specimen, in which ankylosis has taken place; and here is another very good example of the same occurrence, though I do not know that the ankylosis was really produced in these instances by a disease which commenced in the cartilages, or rather, as Mr. Key would say, in the synovial membrane. The application of steam to the part is a beneficial plan, where ankylosis can be avoided, for it promotes the restoration of the functions of the joint, and tends to obviate the stiffness, which is apt to continue a long while after the disease has stopped.

Another form of disease of the joints, is that in which the affection begins in the cancellous texture of the heads of the bones, often set down as *scrofulous*. All the joints are more or less liable to it; but the ankle, knee, and elbow, are those in which it occurs with particular frequency. When the knee is the part affected, there is considerable pain about the head of the tibia, or in the centre of the joint, followed by a general enlargement of it. In consequence of the swelling of the part, and a degree of emaciation, which takes place

in the limb above and below the joint, it seems as if the head of the bones were enlarged; but experience has proved that such is not really the case, and that the appearance depends on the emaciation of the leg and thigh, and the thickening of the synovial membrane and parts external to it. The scrofulous disease of joints is remarkable for the great length of time, during which the skin retains its natural colour; hence, indeed, the term *white swelling*. Ultimately, however, the skin becomes tense and shining, and streaked with dilated tortuous veins. In this stage the joint will also generally be noticed to be above its natural temperature. Frequently before the disease has advanced to suppuration, the joint cannot be bent and extended, but becomes permanently fixed in one position. Thus, when the knee is affected, it becomes generally more or less bent, and cannot be straightened; most frequently it is quite bent, and the patient has no power to change its position. In time, matter forms in the cavity of the joint, which makes its way by ulceration through the synovial membrane, or abscesses sometimes form on the outside of the joint. Then the cartilages are destroyed, and several fistulous apertures take place about the knee, through which the matter is discharged. Sometimes sinuses form, and run to a considerable distance from the joint under the fascia or between it and the skin. When you examine a joint in this state after amputation, besides ulceration of the cartilages, and inflammation and thickening of the synovial membrane and of the cellular membrane external to it, you will find the heads of the bones softened and weakened in their texture, in which is deposited a soft substance, of a caseous yellow appearance, seemingly deposited in the very tissue of the bone, the phosphate of lime being partly absorbed, and this new softer substance secreted in lieu of it. Here is a specimen, in which the ends of the tibia and fibula are in a scrofulous state; a section of the bones would have shown the nature of the disease still better. You will also find in many scrofulous bones, a considerable deposition of bony matter on their outside, in very irregular forms, and sometimes in the shape of spiculæ or icicles. Whenever you amputate scrofulous joints, you will mostly see these irregular bony deposits. They are, as I have said, sometimes very much like icicles, or stalactical processes, and very sharp. These appearances on the heads of scrofulous bones are so common, that I am surprised our museum should be without many specimens of them. In this preparation, you see the nature of the deposits to which I am alluding.

The scrofulous affection of the heads of the bones is, perhaps, more difficult to cure than the generality of diseases of the joints, excepting the organic change, or pulpy thickening of the synovial membrane. The disorder, indeed, is connected with a scrofulous constitution, the rectifying of which is no easy task.

However, this must be attempted, and means to be adopted for the purpose I will describe when I come to the subject of scrofula.

In the treatment of scrofulous disease of a joint, commencing in the heads of the bones you are called upon to keep the part perfectly motionless; this principle applies, as I have before observed, to all diseases of joints. The object is effected either by means of long straps of plaster, or by means of splints. When there is a tendency in the limb to assume a posture, which would let it be of little use to the patient in case of ankylosis, you should endeavour to counteract such tendency with the aid of splints. In addition to these means, blisters should be applied to the joint, and kept open with savine ointment. Or you may employ the antimonial ointment, issues, moxa, and other counter-irritants, which form the common mode of practice. But whenever you find the joint affected with a degree of acute inflammation, you should defer or discontinue the counter-irritants, and trust chiefly to quietude and antiphlogistic measures till the inflammation has subsided. When the diseased process has been arrested by the above methods judiciously put in practice, sham-pooing may be had recourse to, or water allowed to fall upon the part in a column from a considerable height, which plan is to be persevered in for a certain time every day. It is always a rule in the treatment of this disease to open abscesses early, and when you find ankylosis is likely to take place, be sure to place the joint in the posture most likely to let the limb be of the greatest service to the patient.

Coxalgia, or, the scrofulous disease of the hip joint, is generally supposed to commence in the cartilages; but this is, perhaps, rendered doubtful by the tenor of that information, which is derived from Mr. Key's investigations, whence it would seem that cartilage is not susceptible of any primary morbid change itself. I have occasionally been induced to suspect, that the disease begins in the bones, and this is the opinion entertained by Mr. Syme. Mr. Brodie's observations tend to show, that the cartilages are the texture affected, at all events, in a very early stage of the complaint. Mr. Key's dissections lead him to believe, however, that the ulceration of the cartilage is preceded by inflammation of the ligamentum teres. In one case the ligamentum teres was found much thicker and more pulpy than usual, from interstitial effusion; and the vessels upon its investing synovial membrane were distinct and large. At the root of the ligament, where it is attached to the head of the femur, a spot of ulceration of the cartilage was seen, commencing, as it does in other joints, by an extension of the vessels in the form of a membrane from the root of the vascular ligament. The same process was also taking place on the acetabulum, where the ligamentum teres is attached. It is chiefly seen in children between the ages of

seven and fourteen; though occasionally it occurs at an earlier, and also at a much later period of life. One of the first symptoms is pain about the knee-joint, and sometimes there is more uneasiness felt there than in the hip-joint itself. The pain also generally shoots downwards along the inside of the leg, as far as the instep. The pain is so much complained of in the knee, that nurses and careless practitioners will often apply poultices to that joint, without even suspecting that the hip is the true seat of disease. The next thing usually noticed is, that the child begins to limp, and the limb begins to shrink and dwindle away. One remarkable symptom is, that the *glutæus maximus* muscle on the diseased side is always much flattened, and its lower margin less prominent than that of the corresponding muscle of the opposite side. Hence, when there is any doubt about the nature of the case, never omit to examine the posterior appearance of the pelvis and muscles attached to it; and then, if the disease be *coxalgia*, you will observe that difference between the *glutæi* muscles which I have described, viz., the diseased side will be flattened, and its lower margin, instead of being prominent and conspicuous, will be almost effaced. In the early stage, the patient inclines his thigh forwards, as is well represented in this engraving; and, when in the same stage of the disorder, you examine the patient as he lies on his back, it appears as if the limb on the diseased side were longer than the other. Many speculations were once entertained in explanation of this apparent elongation of the limb; but every view then suggested was erroneous. At the present day surgeons ascribe the lengthened appearance of the limb to the position of the pelvis being altered; for, in order to save the limb as much as possible, the patient keeps it suspended, and the weight of it has the effect of drawing that side of the pelvis lower down than the opposite side. Therefore, when you examine the two limbs, in the recumbent position of the patient, the diseased limb appears the longest, because the acetabulum is lower than natural, and the posture of the pelvis oblique. This alteration in the position of the pelvis even affects the spinal column more or less; and, you will find, that it is also more or less distorted by the efforts made to counterbalance the weight of the suspended limb. As the disease advances, pain begins to be felt about the trochanter major, and also in the groin, and the suffering is greatly increased by eversion or abduction of the limb, a fact which Mr. Key dwells upon as corroborating his belief, that the disease begins with inflammation of the *ligamentum teres*; for those movements cannot be endured in the early stage, though flexion and slight inversion cause no complaint. Mr. Key also deems the pain felt on pressing the head of the femur against the acetabulum another proof of the disease beginning with inflammation of the *ligamentum teres*. In

some cases the disease does not advance to suppuration; the morbid changes cease, and a cure takes place, without the formation of any abscesses. Sometimes the disease terminates in ankylosis, also without suppuration. Here is a specimen of ankylosis of the hip-joint, but the particulars of the history of the case are not known. In other instances abscesses form, and then the matter generally passes down behind and below the trochanter major, and often spreads to a great extent down the limb. Sometimes the abscess spreads upwards above the great trochanter, and around the pelvis. Such abscesses commonly burst in various places, as represented in this plate; you see several ulcerated openings, leading by fistulae down to the diseased hip. Sometimes the matter escapes by fistulous openings on the nates, or thigh; but, now and then, the acetabulum, becoming carious, an opening takes place through it, the matter thus finds its way into the pelvis, and, descending by the side of the rectum, bursts near the anus. One memorable case is recorded by Sir Charles Bell, in which not only were the acetabulum and the head of the femur injured by the effects of caries, as usually happens, but, after the disease had advanced to a certain extent, the remains of the head and neck of the thigh-bone passed through the carious acetabulum into the pelvis. This occurrence is represented in the plate, to which I now beg your attention; and in this specimen, the history of which, as I have stated, is not known, a portion of the head of the femur is seen projecting into the pelvis, in consequence of the injured state of the acetabulum. In the second stage of this disease, the bone becomes dislocated; the acetabulum being more or less destroyed, and the *ligamentum teres* and the synovial membrane nearly annihilated. In almost all cases of hip disease in the advanced stage, the *ligamentum teres* suffers. Then dislocation takes place, and this generally happens very suddenly, the limb becoming all at once several inches shorter than natural, with the toes turned inwards. The examples in which the contrary position of the toes is seen, are probably those in which the head of the femur is totally destroyed, or separated from the rest of the bone, and the shaft drawn upwards; but, when the head remains, and is not totally destroyed or separated, the toes are turned inwards. If the head of the femur is destroyed before the shortening, then there may be eversion of the limb. These circumstances are worth remembering. Mr. Wickham, in a treatise recently published on this subject, gives an instance, in which both hip-joints had been diseased, and in which the toes of each limb were turned out. This position he also regards as the invariable one, when a dislocation really happens; for in those cases, where the limb is inverted, he conceives that it is merely drawn across the other. You will find in the advanced stage, at-

tended with dislocation, that the limb is not only sometimes shortened and turned inwards, but also that the thigh is considerably bent upon the pelvis. During these changes, the constitution suffers severely from hectic fever, and not unfrequently a fatal termination is the result. Carious disease of the hip-joint, attended with suppuration in the adult, is seldom cured. In a grown up person, the prognosis is almost always unfavourable if abscesses take place; but children sometimes get through the disease, though suppuration be present. The degree of danger in these cases depends on several circumstances, first, on the extent of the disease in the bone; in some instances, which I have dissected, a considerable portion of the ossa innominata (and not merely the acetabulum and head of the thigh-bone) was diseased and carious. I have seen the os ilium extensively diseased, so that a great deal must depend on the question, how far the disease of the bones has reached. Secondly much will depend on the size of the abscesses; when there is no suppuration, the danger is less considerable, and then even an adult may recover. Thirdly, the degree of hectic disturbance influences the prognosis; and so does the age of the patient; because, if he be an adult, and abscesses take place, he will have but little chance of recovery. You will find, that many children who die of this disease, have at the same time pulmonary tubercles; I attended a young lady a short time ago, who died with disease of the hip, and, on opening her chest, numerous tubercles were found in the lungs.

Gentlemen, the most essential part of the treatment consists in keeping the joint perfectly quiet; this principle is insisted on by all good practical surgeons. If the joint be moved, there will certainly be abscesses, and the disease will take an unfavourable course. In the early stage, you may have recourse to cupping, leeches, and fomentations. These means should enter into the first part of the treatment; you will generally find, when you first see the patient, that there is more or less inflammation about it, from its not having been kept quiet, though the pain is generally referred by the patient himself to the knee; but if you examine the hip, you find a degree of heat about it, and, therefore, antiphlogistic measures will be proper. Such measures appear to be called for by Mr. Key's view of the probable commencement of the disease with inflammation of the ligamentum teres. Afterwards when the inflammatory symptoms have been subdued, nothing is more beneficial than counter-irritation in arresting the morbid process. Frequently, in the course of the case, considerable portions of dead bone will come away; they exfoliate; but sometimes you must wait a considerable time before they are detached. Sometimes portions of the bone crumble away, and you will find small fragments of the osseous texture in the discharge. The best situation for issues is just behind and

below the trochanter major; here they are less inconvenient to the patient than elsewhere, the peas can be kept in very well, and the discharge and counter-irritation in this place will have the best effect. The place immediately in front of the joint, has sometimes been selected for the situation of issues, or setons; but the other is preferred by the generality of practitioners. With regard to the hectic fever, I need not dwell on that subject at present, as I have already given a particular account in a former lecture of its nature and treatment; here the indications are exactly the same as those, to which I formerly solicited your attention.

The last affection of the joints, which I shall describe to you on the present occasion, is *anchylitis*. Anchylitis is of two kinds, *complete* and *incomplete*, or, *true* and *false*. In the *complete* or *true anchylitis*, the articular cartilages are destroyed, and the heads of bones connected together by osseous matter, and consolidated together. The *incomplete* or *false anchylitis* is where the affection falls short of ossification; the stiffness and immobility of the joint depending, not on osseous union of the articular surfaces, but either upon adhesions of the synovial membrane, or upon a thickening of the parts about the joint. Frequently when the cartilages of a joint are destroyed by ulceration, and the surfaces of bone exposed, anchylitis becomes the most favourable termination that can take place. In this point of view, then, anchylitis is sometimes a desirable and salutary event, and the only mode by which a dangerous disease of a joint can be brought to a conclusion. When, however, it follows a fracture that has occurred near a joint, it is to be considered as an event which it would have been desirable to prevent; but, under certain conditions of diseased joints, anchylitis is one of the best things which can happen. Thus in scrofulous caries of the spine, anchylitis is the most favourable result, which we can possibly hope for, because, as soon as it has taken place, we know, that the morbid process has ended, and, indeed, it is the completion of the cure. In coxalgia, white swelling, and scrofulous disease of the spine, it is often to be regarded then as a favourable event. In fractures near the joints, anchylitis should always be prevented if possible, and, for this purpose, you will remember what I told you when I was on the subject of fractures, namely, that passive motion of the joint ought to be had recourse to before it is too late. I may observe, however, that the first thing for preventing anchylitis after fractures near a joint, is to keep down inflammation of the part by antiphlogistic treatment, bleeding, purging, leeches, and cold applications; and afterwards, when all inflammation is over, and the cure of the fracture advanced to a certain stage, you should begin cautiously with passive motion of the joint. The patient must allow the surgeon or an attendant to move the joint gently a certain time every day; but he must not put

his own muscles into action for the purpose, or make any effort himself. Frequently, at the end of three weeks, when a fracture is situated in a joint, passive motion must be thought of.

Some cases are recorded, in which the whole skeleton was affected with ankylosis. You will find in the *Histoire de l'Académie des Sciences*, the case of a child afflicted with universal ankylosis. Though ankylosis of the lower jaw is of rare occurrence, instances of it have been met with; one is mentioned by Eustachius, and another lately came under the notice of Cruveilhier. Here you see an engraving of the skull; the ankylosis was in the right articulation of the lower jaw. The subject of it, an old woman, was not more than eight or nine years of age, when the ankylosis formed, which happened from a blow on the side of the face. You see by the section of the joint, which is exhibited, that there was not merely a deposition of bony matter external to the joint, but that the condyle of the jaw and glenoid cavity of the temporal bone, were actually consolidated into one solid mass. Notwithstanding the ankylosis, the patient contrived to masticate with tolerable facility, by pressing the food against the alveolar processes with her tongue. As for her speech, it was very perfect, so that she managed to live to a good old age with a great deal of comfort.

MR. SALMON'S REPLY TO DR. O'BEIRNE.

PATHOLOGY AND DISEASES OF THE RECTUM.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I feel that my apologies are due for not replying earlier to Dr. O'Beirne's letter; the truth is, I have have not had the documents necessary to complete the answer until very lately, added to which, my leisure has been completely occupied by the affairs relative to my resignation at the General Dispensary, which circumstances will, I trust, be received as my excuse. Requesting your insertion of the accompanying communication at your earliest convenience,

I remain, gentlemen,

Your obedient servant,

FREDERICK SALMON.

12, Old Broad-street,
Nov. 30th, 1833.

Prior to the perusal of this letter allow me to suggest to your readers to refer to the numbers of your journal published on March 23rd and 30th, April the 20th, and August 24th, of the present year; in the two first of these they will find your review of "Dr. O'Beirne on Defecation;" in the third, some observations of mine upon that review, and in the last, a letter from Dr. O'Beirne, addressed to me.

Desirous of avoiding useless controversy, I shall, in my reply to that letter, confine myself to such points only as I feel it necessary to substantiate, first, for the purpose of science, and, secondly, with the view of maintaining that respect, which every man of character ought to feel he owes to himself. And though I should wish to have entered primarily upon the most essential of these two points, I do not think I ought to do so, without first disowning, in an unreserved manner, the applicability of the preliminary observations in Dr. O'Beirne's communication; observations neither called for by "the general nature and tone of my remarks," nor substantiated by the confident and erroneous assertion, that I sat down to display the fallacy of his "Doctrines," "without having first read his work." And, indeed, had I acted in so injudicious a manner, he has no cause for complaint, neither have I anything to retract; since I addressed you, not upon the general contents of his volume, but upon what he with truth has denominated, "a highly favourable review of it," and in which review, the substance of his opinions, so far as the matters in dispute between us are concerned, is accurately set forth.

He commences by accusing me of "two important mis-statements." First he says, "I do not deny that the rectum is intended to contain fecal matter, because every one knows that the feces must pass through it." Now, without being disposed to cavil about the construction of words, a reference to Walker will show, that to contain, means to hold, and I presume Dr. O'Beirne will not deny that the bowel may, with perfect correctness, be said to hold "the little fecal matter," which he states "may be found in its pouch, but in no other part;" an admission rather irreconcilable with the following observations extracted from his book. "I have been led to examine the rectum of healthy persons, at different times of the day," and in every instance when the tube presented the least appearance of feces, this was confined to that portion of its upper extremity which had entered the sigmoid flexure." In another place, he says, "surgeons find it necessary to pass a finger into the rectum for surgical processes, &c. &c., yet it is a fact that it has extremely rarely happened that the finger has encountered feces." Again, "it is also a fact, familiar to apothecaries and nurses, that the pipe of an injection machine, however long it may be, is rarely, if ever, soiled with fecal matter." And when alluding to examining the bowel, he remarks, "the tube could be moved about freely in a space which, on introducing the finger, was ascertained to be what anatomists call the pouch of the rectum in a perfectly open and empty state*." Doctor O'Beirne

* Though we have given a most favourable opinion of Dr. O'Beirne's views on defecation, and still maintain that most of them

goes on to say, "so far from denying that the rectum acts as an antagonist of the sphincter," the view he takes of it in his reply, "*actually makes it the only antagonist of the sphincter muscles.*" And how does he prove this? not by considering the bowel in the light it has hitherto been estimated, a receptacle for the fæces, in common with the rest of the alimentary canal, expelling them by contractility, and thus overcoming the power of the external sphincter; but by showing, "that while the intestine is contracted and empty, its upper annulus or extremity is engaged, and not, as has been supposed, the sphincter ani muscle, in opposing the action of the diaphragm," &c. &c. Now it is evident, that so far from the rectum, when empty, acting as an antagonist to the sphincter, inasmuch as it is in its natural state of passive contraction, it can only be considered to act in unison with that muscle. So much for my two important mis-statements.

Dr. O'Beirne appears to estimate very lightly my observations on the process of defecation, which he says, "contain little of novelty." I am inclined to go a great deal farther, and say they contain nothing of novelty; this, however, is of no moment, the question is, do they satisfactorily account for that process? and if so, do they not expose the erroneousness of his theory. Here I rest content with the decision of all professional men of candour and judgment.

He proceeds,—"Assuredly I could not possibly have read his work," when "I put the four questions respecting the rectum;" for, "if I had, I should have found, that he discussed the three first points at great length, and explained them on the only principles upon which it is possible to explain them correctly." Of the peculiar force of the bowel (the first of these four questions) Dr. O'Beirne says nothing; as to its extreme muscular power (the second question) he writes in his book, and the words are printed in italics.—"*It is therefore both an anatomical and a physiological fact, that this intestine exceeds every other part of the intestinal canal, in the number and strength of its muscular coats, and consequently in muscular power.*" Now if any of your readers will take the trouble to refer to the chapter in my work on Stricture of the Rectum, which treats of the anatomy and physiology of the bowel, they will perceive that the remarks of Dr. O'Beirne, which may be considered as illustrative of this fact,

will lead to the happiest results in the practice of medicine, yet we cannot agree with him on all points. We cannot assent to his doctrine, that the rectum is not a receptacle for the fæces, because we, and every one who has experience in the practice of obstetrics, have, during parturition, repeatedly detected fæcal matter in the rectum, nay, the bowel is often impacted with it.—Eds.

contain nothing new. Neither can I find that he assigns any reason *why* the rectum should be larger at its anal extremity, which was the third question. The greater abundance near to this part of the absorbents, he "formally denies," and accounts for the prevalence of the mucous glands (which two points embrace my fourth question) by stating, that, "common sense points out that an extra sprinkling of the mucous glands would be particularly required at a point where a considerable mass of dry and solid excrement was about to pass through so small an outlet as the anus." With regard to the absorbents, I believe them, from what I have seen, to be more abundant at the inferior part of the rectum, and I hope ere long to demonstrate that this is the case; if, however, the bowel does not *retain* the fæces, but only *contains* them, for the very limited time they are passing through its channel, I confess I do not see how the mass, while so evacuated, is to become "dry," or, the necessity for that increase of the mucous glands near the orifice, which Dr. O'Beirne admits to exist. I think it would have been more rational to have placed the superabundance at the commencement of the gut, or where he considers the fæcal matter accumulates.

Dr. O'Beirne next enters upon the question of whether or not, the rectum is a *dépôt* for the gradual accumulation of fæces, and states, that I sustain the former opinion, first, "by giving as his an entire passage which is not to be found in his book;" a grave charge, and one which, if true, would justly entitle me to unlimited censure. But what is the fact? That when replying to your remarks, I quoted some of those verbatim, which, as it should be presumed, he has unknowingly and consequently unintentionally charged me with giving, "as his," a mistake nevertheless somewhat remarkable, considering that its author had taken above three months to frame the letter he addressed to me. 'Of the opinion conveyed in the following passage in my first letter,—"*hence*" (alluding to collections in the bowel) the symptom, "*irritable bladder which invariably accompanies stricture in either of the two upper curves of the rectum,*" he summarily says,—"*I deny this to be the fact.*" And why?—Because he "has frequently examined the rectum of persons labouring under irritable bladder, and has never found it to contain fæces;" and, because "it is well known that such an affection of the urinary bladder exists without constipation;" and, it does not appear that the comparatively rare cases in which constipation is caused by indurated fæces accumulated in the rectum, have been attended with irritability of the bladder." This is, indeed, sound reasoning, and a satisfactory refutation of my position!

Notwithstanding the "thirty years' experience" which your correspondent states he has passed "in the study and practice of his profession," I must again say, that "I think it *questionable*" if the sphincter is ever de-

stroyed by *sypilis*. Whether such an effect took place in former times, when the treatment of the disease was ill understood, is a proposition I am not able to discuss. I am, however, able from experience to assert, that so far from a person affected with *carcinoma recti*, "rarely if ever" passing "his stools involuntarily," he will be necessitated to void them every ten or twenty minutes; in fact, in the later stages of that appalling malady, he loses the power of retaining them altogether. I have an example of this at present under my care, in which the afflicted patient, in answer to my inquiry of—Do you think your bowels less irritable? replied,—“Perhaps they are so; I only had forty-one evacuations between eight o'clock last evening and eleven this morning.”

“Why,” asks Dr. O'Beirne, “have you not adverted to the proofs I have adduced in *Prolapsus Ani*,” and, “the operation for fistula,” &c. &c.? Simply, I answer as before, because I was not analysing his book, but remarking upon your review of it. Yet in reference to the first of those two points I may observe that there is no such disease as *Prolapsus Ani*; the *Anus*, as I state in my practical observations on prolapsus of the rectum, is but the aperture through the sphincter which cannot be prolapsed; and as to the division of the sphincter in the cure of fistula, reflection shows that the muscle being circular, its division at any particular part does not destroy, though it weakens, its retentive power.

In reference to the observations Dr. O'Beirne makes on the following passage in my first letter, “neither in my limited judgment is his examination of the rectum at all conclusive of the correctness of his opinion, considering it as I do, to be anything but a scientific exploration of the part,” I cannot do better than request your readers to refer to my former remarks, which I should suppose, must to any person conversant with the form, natural calibre, and relative position of the bowel, be conclusive; to argue further upon this point would be a useless waste of time. Respecting the causes of contraction of the sigmoid flexure, I repeat that I have long since stated they are similar to those Dr. O'Beirne is reported in your review to consider them; to wit, “morbid irritation,” “constipation,” “frequent accumulations,” “drastic medicines,” “peculiar form,” and lastly, “a narrowness of the sigmoid flexure,” which I believe to be “sometimes congenital.” He, however, writes, “that not having seen any report of your lectures, I can only reply to this point by turning to the second edition of your work, in which I cannot find that you have qualified your opinion by the word *sometimes*, from which circumstance it would really appear that the interpolation is of very recent date, and that you are likely to come round to my views of the matter.” Upon the two first points Dr. O'Beirne may be instructed by a reference to the pages of the number of that most useful periodical the *Lancet*, as published on the 26th

of May, 1832; and upon the last point I would suggest, that it is not usual to quote the second edition of a book of which a fourth has been published since the month of April last; furthermore the sense of the paragraph which Dr. O'Beirne says I have interpolated, is as clear, even in the first edition, as the sun at noon-day; when in allusion to appearance of stricture even in children, I write, “so early have I witnessed this, that I should think the disease congenital.” If Dr. O'Beirne will peruse the fourth edition of my book, I feel satisfied he will perceive the inapplicability, not to say the offensiveness, of the remarks contained in this part of his letter.

I now come to the point which is of more consequence than all the others put together; to wit, whether or not stricture of the rectum exists within reach of the finger. There Dr. O'Beirne has gone much further even than was necessary, and replies with equal candour and incaution, that if “either of these gentlemen (whom he names) informs me that you possess preparations showing distinct thickened and shelf-like projections, from any part of the interior of the rectum, lower down than its upper extremity, I hereby bind myself to at once publicly recant my error. But if, on the contrary, either of these gentlemen should inform me that your preparations exhibit nothing more than a greater or less degree of uniform thickening of the parietes of the intestine, and extending to a greater or less degree downwards, without any distinct, thickened, and shelf-like projections, internally, I shall expect you to adopt the same course.” Now your readers will at once perceive that the challenge conveyed in the first division of this paragraph, absolutely goes to the extent of denying that stricture of the rectum exists below its union with the colon; a latitude of opinion which even I had not given Dr. O'Beirne credit for, since I merely contended for the existence of permanent stricture in the lower part of the rectum. It likewise appears from the meaning conveyed by the second sentence of the paragraph, and which alludes to the morbid anatomy and situation of stricture, that Dr. O'Beirne is but ill acquainted with those matters, else he would know that it is exceedingly unusual to find any other result in the two upper thirds of the rectum, how much soever it may be contracted, than an uniform thickening of its parietes, from depositions in the cellular tissue between the mucous and muscular coats, by reason of the longitudinal fibres preponderating at those points; while circular fibres lie most commonly within reach of the finger.

Immediately after reading Dr. O'Beirne's letter, I wrote to Mr. Bransby Cooper, one of the friends he named (although I should have considered that if Dr. O'Beirne, or any respectable professional man, declared publicly that he had certain morbid parts in his possession, it would have been conclusive), and requested him to inspect, in conjunction with

Dr. James Blundell, several preparations illustrative of stricture of the rectum; subjoined is their testimony. Finding they differed so materially, I obtained Mr. Stanley's opinions, which also is annexed. All of these documents I shall feel obliged by your giving publicity to at the foot of this letter.

I before stated, that "when the rectum is empty, its muscular coat is naturally in a state of *passive* contraction, which obviously retards rather than facilitates the passage of the stools," and "that any one who is not practically accustomed to examine the rectum may mistake the natural contraction of the gut for stricture, and for this reason; the mucous tunic is not indued with any material contractility, and is therefore, during the period of the passive contraction of the muscular coat, thrown into numerous folds, which vary in number and size; sometimes these are of a circular shape, at others they form prominent and irregular ridges in the bowel;" I add in postscript, "Morgagni has denominated these the columns of the rectum." It is apparent, upon the face of these remarks, that I never meant that distinguished anatomist applied the term columns to the circular folds, *because* they were of such force, but that he gave that appellation to the mucous folds generally, the circularly contracted state of which I instanced as an exception to their usual condition. Dr. O'Beirne, however, would fain make your readers believe I was ignorant of the usual forms of the folds of the rectum, which he says, "cannot, it is obvious, oppose any resistance to the passage either of the finger or the tube." I confess myself of a different opinion, believing as I do that an introduction of an instrument, much less in calibre than the size of the channel through the bowel when extended, is likely, particularly in the hands of an inexperienced operator to be hitched in the sacs, formed by the corrugations of those folds, especially, if to use Dr. O'Beirne's words, "the natural state of the rectum be one of *forcible* contraction," which I contend it is not, but that, when empty, it is in a state of passive contraction; a fact he complains "I avail myself of as if it were well and generally known," which it surely is, or if not, certainly ought to be.

Dr. O'Beirne admits a "bougie of the largest size will often pass up and dilate the healthy rectum, without difficulty or pain;" yet he considers the bowel, when empty, to be in a state of *forcible* contraction, which to my mind is not very intelligible; for, if the rectum be thus closed, considerable force must be used to open its channel, more particularly if the dilating instrument be of a small size, by reason of which, it offers less opposition to the bowel stimulated from its introduction to eject its contents, but this my former letter fully illustrates.

I must decline commenting upon the remaining passages in Dr. O'Beirne's letter, they are perused by me more in sorrow than in anger; or

accepting his challenge of entering into a controversy respecting his opinions, which would, in all probability, lead to a much greater sacrifice of time than I am able conveniently to command; but, I beg to assure him, I am actuated by no desire of upholding "my own views," or "of assailing the doctrines of others," neither is it "my wish to prejudice the minds of many against views which are perhaps eventually found to be much sounder or more useful" than my own; but that, as far as I am concerned, your readers will consider this is "a hypothetical case." My object has been, as I trust it ever will continue, to further the interests of science, and by such means alleviate the sufferings of mankind. If by exposing the errors into which your respectable correspondent has fallen, or my own ignorance of a class of diseases which is well known, I have extensively, and I trust I may without presumption add, serviceably studied, I have contributed to such desirable ends, it is enough: the judgment upon these points rests, as it is right it should, with the unprejudiced, the competent members of our profession.

I am, Gentlemen, respectfully,

Your obedient servant,

FREDERICK SALMON.

12, Old Broad-street,
Nov. 29th, 1833.

CORRESPONDENCE.

No I.

Dr. Blundell's Opinion.

"Having, at the request of Mr. Salmon, examined certain preparations in his collection marked A, B, and C, respectively, and intended to demonstrate the existence of Stricture of the Rectum, I beg to make the following statement of the appearances which I now observe in the preparations as they stand before me.

A

"Exhibits a great part of the rectum with portions of contiguous organs; the internal orifice of the urethra, in situ; the lower and middle part of the vagina; a large portion of the peritoneum, covering, as usual, the upper and middle part of the rectum in front; the sphincter ani, the anus, and contiguous perineal integument, with several hairs growing upon it at the very verge of the anus.

"In this preparation there is a distinct annular contraction, as if produced by a packthread drawn with moderate tightness round the bowel, closing in so much as to preclude the insertion of the little finger. This contraction is situated about two inches and a half above the outer verge of the anus, rather less than more, and is decidedly within reach of the fore-finger, independently of the help which might be derived from urging.

"Immediately above the stricture an incision has been made in the side of the rectum, the thickness of which is visible, and exceeds one-eighth of an inch; and the inner membrane,

also exhibited, seems evidently, in one part of it, to be destroyed by ulceration; and, in another, where it remains unbroken, its structure is changed, being roughened and thickened.

B

"In preparation B, apparently the entire rectum and a part of the sigmoid flexure of the colon, together with the womb and vagina, throughout the greater part of its length (both in situ, with respect to the rectum), are carefully exhibited. In this preparation, either the entire rectum, or certainly all excepting the upper portion, where it is continued into the sigmoid flexure of the colon, is exceedingly thickened, and so contracted throughout the whole of the thickened part, that the little finger, especially in the inferior portion of the rectum, could not be passed along it without some violence. Where there has been most deposit, the coats of the bowel exceed in thickness three-fourths of an inch. Various sinuses run in various directions, one apparently opening into the vagina. The uterus and vagina lying in situ upon the rectum, seem to mark distinctly that part of the rectum which is most contracted and thickened, and which, as before described, is the inferior portion clearly within reach of the fore finger, which, indeed, on making an examination, must evidently bear upon it immediately on passing the anus.

"A cursory observation of some of the other preparations appeared to confirm the observations made on the two preceding, but they were not examined with the same care.

"JAMES BLUNDELL, M.D."

(The original.)

No. II.

Mr. Bransby B. Cooper's Testimony.

"Having been requested by Dr. O'Beirne to give my opinion upon a point at issue between him and Mr. Salmon, respecting stricture of the rectum, I submit to the task, as the subject is involved in considerable physiological and pathological importance.

"If I understand the point in question correctly, it is,—Whether or not organic stricture ever occurs below the upper portion of the rectum; Dr. O'Beirne being of opinion that it does not, while Mr. Salmon considers that it does. It is necessary, therefore, to notice what Dr. O'Beirne means by "organic stricture of the rectum;" and, from reading his work, I understand the following to be the conditions by which he characterises this disease.—"A deposition of adventitious matter originating in the submucous tissue of the rectum, and subsequently becoming organised, implicates the unvascular and mucous coats, producing shelf-like projections into the cavity of the bowel, so as to narrow its calibre, and occupy either the whole or only a part of its internal circumference."

"Mr. Mayo, in his recently published work on Injuries and Diseases of the Rectum, page 165, gives very nearly in the same words his

definition of permanent stricture of the rectum; and thus far Mr. Mayo and Dr. O'Beirne agree in the formation of organic stricture.

"Dr. Blundell, at the request of Mr. Salmon and myself, on the part of Dr. O'Beirne, examined Mr. Salmon's morbid collection, to learn whether or not he possessed any preparations demonstrative of such morbid changes below the upper portion of the rectum. The result of this investigation leads me to say, that no preparation which I saw of Mr. Salmon's presented the appearances of organic stricture as above quoted. One of the preparations which I examined was a specimen of thickening of the parietes of the rectum, concomitant with ulceration, and involved in the disease of the neighbouring organs, particularly of the vagina, into which a sinus opened.

"Such a disease Dr. O'Beirne has fully described at page 35 of his work, and points it out in contra-distinction to the shelf-like projections produced by the diseased mucous membrane of the organic stricture. The latter kind only involving a portion of the bowel, leaving the remaining part of the calibre free from disease, and portraying, therefore, a very different state from that disorganisation which attends ulceration, in which the surrounding tissues and organs are liable to be affected.

"The specimen of thread-like constriction which I saw, producing the distinct circular contraction, I have no hesitation in pronouncing spasmodic, and therefore not referable to organic stricture.

"The observations, I think, I may say bear a great resemblance to those made by Dr. Blundell upon his inspection of the same preparations.

"BRANSBY B. COOPER."

(The original.)

No. III.

Mr. Stanley's Testimony.

"DEAR SIR,—Agreeably to your request I have examined the several preparations you possess of disease in the rectum, and have selected the following for particular description.

"1st. Specimen from a female.—About two inches and a half above the anus, there is a contraction of the rectum in its whole circumference, and to the extent that it is here reduced to about one-third of its natural size. The contraction occupies only a line in the circumference of the intestine, consequently its outer surface presents an indentation similar to the appearance which would result from tightly drawing a piece of string around the intestine. Immediately above the contracted point, the bowel is dilated much above its natural size; the coats of the intestine are here generally thickened, but, for some way above the contraction, there is superficial ulceration of the coats of the intestine is such as might be considered to be the result of simple inflam-

mation, presenting no character of malignant disease.

"2nd. *Specimen from a male.*—This specimen presents all the characters which have been expressed in the description of the preceding specimen, from which it differs only in the circumstance of the contraction of the rectum being to a greater extent, it will only admit the passage of a middle-sized urethra bougie.

"3rd. *Specimen from a male.*—The lower part of the rectum, to the extent of three inches and a half from the anus, is uniformly and considerably contracted. The mucous membrane is removed by ulceration from the whole of the contracted part of the intestine. Several fistulous passages extend from the ulcerated parts of the bowel to the margin of the anus.

"I remain, dear Sir, yours very truly,
"EDWARD STANLEY."

*Lincoln's Inn Fields,
Dec. 4, 1833.*

NO. IV.

"At the request of Mr. Salmon I examined some of his morbid preparations illustrative of stricture of the rectum. Ten of the specimens leave no doubt of the occurrence of stricture in the lower intestine. One of these shows a considerable narrowing of the rectum below the sigmoid flexure through the whole extent of the intestine, the parietes are better than three-quarters of an inch in thickness, and the canal is so reduced as scarcely to admit the passage of the little finger through some parts of it. In another preparation, there is a well-marked annular contraction, about two inches and a half from the verge of the anus, similar to what has been termed the pack-thread stricture. The tissue about this contraction is abnormally dense, and the side of the bowel is incised superior to the obstruction, where it is an eighth of an inch in thickness, and this change of structure in and about the contraction, proves, in my opinion, that the stricture was not caused by spasm. In a third specimen there is a projecting irregular stricture, about an inch and a half in length. From these and the other preparations I am perfectly convinced of the existence of stricture in every part of the rectum. "M. RYAN, M.D."]

ON THE EFFICACY OF THE SECALE CORNUTUM IN HÆMORRHAGE AND LEUCORRHŒA, AND ON ITS EFFECTS IN GONORRHŒA.

BY G. NEGRI, M.D.,

*Read before the Medical Society of London
Monday, December 2, 1833.*

On the Efficacy of the Secale Cornutum in Leucorrhœa.

ON the employment of the secale cornutum, and on its efficacy in leucorrhœa we shall

limit ourselves to some general remarks, which are the result of our experience on this subject, without entering into any detail of the singular cases which occurred under our observation.

Although the secale cornutum will be found one of the most valuable remedies in the simple form of leucorrhœa, even of a very long standing, and which have resisted many other means, still its efficacy on this kind of diseases is not so rapid as in hæmorrhages. This would have been almost expected as a matter of course, from the more chronic character of the former complaint. Therefore we found it more convenient, and we may say even more safe, to give it in small doses, as five or six grains two or three times a-day, rather than in larger and more frequently repeated ones. Thus the remedy may be continued for a long period without any inconvenience, and with regular advantage. In leucorrhœa as well as in menorrhagia, we must remember, that the ergot of rye has also a peculiar power over the fibrous texture of the womb, and that pains and spasmodic contractions of this organ may be induced, and then symptoms of metritis, and even an increased discharge, may eventually take place. Then it is of the utmost importance, in leucorrhœa also, to allay any state of inflammation, or of local irritation, by those therapeutical means, which may be required by the particular symptoms of each case, before we have recourse to the secale cornutum.

We find in practising, that some patients could not take at first any dose of this remedy without severe pains being induced in the uterine system, when, after having used other remedies for a certain time, they could take the secale again without the least inconvenience, but, on the contrary, with a decided and progressive advantage on their general state of health.

In one of these patients the os uteri was partially open and indurated, and very tender on the left side of its margin: when the finger pressed over this point acute pains were excited, darting from that part to the right iliac region. We used in this case the extract of conium with the sulphate of iron, with great benefit, and, after this morbid sensibility was subdued, we gave again the secale cornutum for the remaining leucorrhœa with decided benefit, and without any more inconvenience, although continued for a long time. We have lately seen this patient, and her general state of health has wonderfully improved; she feels a great deal stronger, and the white discharge is almost entirely gone; we confidently expect to see her in a short time cured by the ergot of rye, which now she only takes twice a-day.

Out of ten cases of leucorrhœa, of which we kept regular notes, the ergot of rye has failed in three. But, in all probability, that happened more from want of experience in the judicious employment of the remedy rather than from its inefficacy.

Of these three unsuccessful cases, two were cured afterwards by other remedies; but one had never been permanently well, either by the ergot of rye or by any other means employed for a long time, both by ourselves and several other practitioners. In this singular case, the *secale cornutum* appeared to have induced once menorrhagia, after which the patient was better from the white discharge for a little while. Amongst the other things we tried repeatedly the injection of nitrate of silver, as recommended by Dr. Jewel, but without any good effect, and as it appeared to this gentleman very extraordinary, we recommended her to the doctor himself, but we do not know the result.

The *secale cornutum* has been successfully employed in leucorrhœa by our colleagues at the St. John's Dispensary, and our friend Dr. Ryan has even used it in private practice with the greatest advantage.

On the Effects of the Secale Cornutum in Gonorrhœa.

About the *modus operandi* of the *secale cornutum* in the above classes of diseases, Dr. Spajrani expressed his opinion in the following way, leaving however this subject for subsequent inquiries. "I am (says he) rather inclined to believe, that this remedy does not act either as an astringent, or as a stimulant, but more as a sedative on the capillary vessels, and for this reason it may be conveniently used in *certain* instances of active hæmorrhage and of vascular congestion, where exists a state *approaching very much to inflammation*; but yet it is not to be used in instances where some *acute inflammation is present*, for which stronger means must be employed."

With the view of ascertaining these therapeutic principles, and from the advantage already obtained by the ergot of rye in leucorrhœa, we thought we should not incur any great risk by trying it also in gonorrhœa, at first in females and then, if not injurious, in males. It is true that the preternatural secretion of the mucous membrane of the genital organs in gonorrhœa, is induced by a specific virus, but still we readily believe that its essential pathological character is inflammatory. Therefore no better opportunity could be obtained for ascertaining the supposed *modus operandi* of the *secale cornutum*, than to use it in a disease of acknowledged character, and in which we could actually see the effects which might be induced by it.

The following cases will give an idea of the result of our enquiries on this subject.

CASE I.—Mary C., married, admitted to St. John's Dispensary on the 9th of May, 1833. She has been ill with gonorrhœa for about three weeks; she caught the disease from her husband, and had been under our care some months ago for a similar complaint, induced by the same cause. She complains of shooting pains through her womb and loins, with ardor

urinæ. She has been regular three weeks ago, and has never been subject to leucorrhœa. An opening medicine was ordered, and she was directed to take afterwards vi. grains of the *secale* three times a-day.

May 13th. She is a great deal better; has now no discharge; had no giddiness, but only pains in the lower part of the abdomen, and a kind of cramp of the womb; feels still pain in making water. The same powders to be taken only night and morning.

20th. No discharge; complains still of shooting pains in the womb; *secale* suspended, and only some supertartrate of potash to be taken as an imperial drink. On the 29th she was taken unwell, but the catamenial discharge was very scanty and pale, after which, on the 6th of June, had a slight return of the discharge, which was gradually arrested by the *secale* in moderate doses. She was discharged cured on the 25th of July.

CASE II.—Mary Anne C., æt. 26, single, admitted on the 9th of May, 1833.

Has had gonorrhœa for nearly two months; has not been regular for several months, and has been subject to leucorrhœa; bowels regular. Six grains of the ergot of rye were ordered to be taken every four hours.

13th. The discharge ceased after having taken four or five powders, and has not returned since: proved no inconvenience by taking her powders. They were ordered to be taken only night and morning.

30th. She menstruated on the previous day, and was left without medicine.

June 6th. Has no discharge at all, and says she is quite well. Discharged cured.

CASE III.—Harriet R., æt. 27, married, admitted on the 20th of May, 1833.

Has had gonorrhœa four years ago, from which she was perfectly cured. She was taken ill again with the same complaint, caught from her husband about ten weeks ago, for which she has been treated, as an out-patient at St Bartholomew's Hospital, under Mr. Lawrence. Balsamic medicines and mercurial pills were given to her, from which she was much relieved. Now the discharge is thin and white, when before it was yellow and thick. Complains still of some starting pains through the womb, but has less pain in making water; complains of pain in her right leg, where there is inflammation of the periosteum on the shin bone, probably of a syphilitic character; her bowels being costive, a cathartic powder was ordered, and five grains of the *secale cornutum*, to be taken every four hours, beginning the following morning.

23rd. The discharge is less; she feels sick, after having taken her powder, and complains of being very weak.—Pergat.

30th. The discharge is less than on the preceding day of attendance; she has now no pain in making water, but continues to feel sick after taking the powder; has had no

giddiness. Continue the powder three times a day.

June 6th. The discharge has ceased. The secale was suspended, and the mercurial treatment was adopted for what we thought a syphilitic complaint.

CASE IV.—John F., æt. 40, a baker, admitted on the 21st of June, 1833.

Has had gonorrhœa about six times; it usually resisted every remedy, and once he had it for nine months; now he has had gonorrhœa for about three weeks; has great pain and scalding in making water, and generally some drops of blood follow; has a great deal of discharge, and the orifice of the urethra is reddened and swollen; in the night he has painful erections. Five grains of the secale cornutum to be taken every four hours.

22nd. We saw again the patient. He has taken five powders; the discharge is not abated, but he thinks he has less pain in making water.—Pergat.

28th. He has taken about sixteen powders; he has no pain in making water; he has had still painful erection at night, but the orifice of the urethra is a great deal less red, and the discharge considerably abated; he has now no inconvenience, except a very slight feeling of warmth in making water. He continued the medicine in ten grain doses every four hours until the 11th of July, when he was nearly well, and requested to be discharged.

The patient was under Dr. Ryan's care, and was repeatedly seen by ourselves and colleagues.

CASE V. William M., æt. 24, admitted on the 22nd of August, 1833. Has had gonorrhœa about twelve months ago; has now been ill, for the second time, with the same complaint for a fortnight; discharge copious, yellow and thick. Five grains of the secale cornutum to be taken every three hours.

26th. Is just the same, but does not feel worse.—Pergat.

September 2nd. He is a great deal better.—Pergat.

12th. Discharge scarcely perceptible. Continue the powders, but only one three times a day.

16th. Discharge almost gone.—Pergat.

He went on taking his powders till the 10th of October, when he asked for another dose of them, to be taken night and morning, having still some little discharge only in the morning. This patient, who was very attentive, and appeared much satisfied with his powders, having not returned, we have good reason to believe he is now doing very well.

CASE VI. William S., æt. 28, admitted on the 4th of September, 1833. Was taken ill with gonorrhœa a week ago; feels great pain

in making water; discharge copious, yellow, and thick.

R. Pulv. secalis cornuti gr. v, 3a. q. h. s.

16th. Discharge thinner; pain in making water gone.—Pergat.

23rd. Discharge increased; secale suspended, and prescribed the *mistura balsamica*.

October 7th. Discharged cured.

CASE VII. Only a few days ago we had in private practice a patient affected by gonorrhœa for the first time. The symptoms were not severe; the discharge moderate. Being an individual of a delicate constitution, and of very regular habit, we expected to do some good in this case with secale cornutum. Three grains of Battley's extract were ordered to be taken every three hours. The following day the discharge appeared a great deal less, and the remedy was continued. Two days afterwards the discharge increased, as well as the ardor urinæ, and he had painful nocturnal erections. The remedy was brought to five grains every three hours, but was soon afterwards suspended, and other means adopted. In this case the secale cornutum certainly increased the severity of the symptoms; and the discharge, which was moderate at first, and thin, became afterwards copious, thick, and sometimes tinged with blood. The pulse was also feverish and sharp, the skin warmer than naturally. This patient is usually of a very costive habit, but has great aversion to take purgatives; had we used them previously, or simultaneously with the secale, we could perhaps have obtained a better result. This was necessarily done after we had resorted to the other usual means generally employed for that complaint.

SHORT NOTES OF CASES BY DR. RYAN.

CASE VIII.—"M. M., æt. 22, married, has contracted gonorrhœa from her husband; became a patient under my care at St. John's Dispensary, Sept. 12th, 1833. Is two months' ill. She was ordered 3 iss of secale in twelve powders, one to be taken three times a-day.

"16th. Discharge nearly gone.—To continue.

"23rd. Discharge has entirely ceased."

CASE IX.—"Charles C., æt. 22, has suffered from gleet for six months. Commenced the secale Sept. 17th, 1833, and on the 23rd was nearly well. He has taken a variety of medicines, but nothing stopped the discharge so rapidly as the powders."

CASE X.—"G. S., æt. 34, has been six months affected with gleet. Commenced the secale Oct. 30th, 1833. Took fourteen powders without any benefit. This was a morning patient, and had the medicine of a druggist, which, perhaps, was bad."

CASE XI.—"A. B., æt. 34, has suffered

from gleet for eight months. He was cured by twelve doses of the *secale cornutum*."

CASE XII.—"J. A. L., æt. 19, applied to me Nov. 5th, 1833. Has gonorrhœa for the first time; symptoms severe. Ordered the *secale*.

"8th. Discharge more copious; ardor urinæ severe.—*Secale* omitted.

"Ordered carbonate of soda in barley-water or linseed tea.

"In this case I did not expect much benefit from the *secale*, but was resolved to try it. Every medical practitioner is aware, that a first gonorrhœa is much more severe and indomitable than when the patient has had the disease frequently, or when the acute symptoms have ceased. But, as I have known cubebs repeatedly arrest gonorrhœa in the acute stage, I saw no objection to employ the *secale cornutum*."

From the above facts it appears to us quite evident, that the *secale cornutum* has a peculiar action on the mucous membranes; but if exhibited when there is a state of acute inflammation, their morbid secretion may be considerably increased. On the contrary, when a more chronic form of inflammation exists, the *secale cornutum* may have a beneficial influence in arresting their preternatural discharge.

These deductions being in perfect accord-

Tabular Form indicating the result of all the Cases of Hæmorrhages and Leucorrhœa which came under our observation, from the 16th of April, 1832, to the 4th of Nov., 1833, and were treated with the Secale Cornutum.

Different Forms of the Disease.	Total number of Cases.	Successful Cases.	Unsuccessful Cases.	Remarks.
Menorrhagia.	12	8	4	<p>* We include in the whole number the case treated by Dr. Macmichael, at the Middlesex Hospital.</p> <p>† We put down as an unsuccessful case the first attack of the disease of Elizabeth Pilcher (Case VI.), although in the second, the <i>secale</i> turned out very beneficial when given in proper doses.</p>
Hæmorrhage from the rectum.	2	2	—	
Hæmatemesis.	4 *	3	1 †	
Epistaxis.	1	1	—	
Hæmoptoe.	1	1	—	
Leucorrhœa.	10	7	3	
Total.	30	22	8	

Note.—We did not put down in this table the cases of gonorrhœa because they were related merely to show the effects, and not the efficacy, of the *secale cornutum* on that disease. All we can say, from the limited number of observations on this subject, is, that perhaps the ergot of rye may be found of some service in the more chronic form of that disease.

Of the unsuccessful cases of menorrhagia, the first was a woman who had a copious loss of blood from the vagina, with great tenderness at the lower part of the abdomen, and pains round the groins and loins. Her pulse was such as would have induced us to bleed her, had we not wished to try the *secale*

cornutum in this case, which was the second that had come under our observation, since we began to employ this remedy. Five grains of the *secale* were ordered to be taken three times a day. The powders were taken for two days, and the pains and loss of blood were considerably increased. They were suspended;

ance with what has been already remarked on the efficacy of the ergot of rye in hæmorrhages and leucorrhœa, we think Dr. Spajrani's assertions on this point pretty correct. If any sedative or anti-stimulant property on the capillary vessels of the mucous membrane may be ascribed to the *secale cornutum*, as Dr. Spajrani is inclined to believe, we do not know. It is true, that in Case IV. of gonorrhœa, where did exist redness and swelling round the orifice of the urethra, this appearance subsided under the influence of the *secale*; and that, in some instances of hæmorrhage, the patients were complaining of great general prostration and faintness; but others, on the contrary, felt stronger, and their pulse appeared to us more excited; when, in Cases VII. and XII. of gonorrhœa, the inflammatory symptoms were considerably increased. Are some of the former symptoms to be ascribed to the narcotic influence on the nervous system, rather than to any real sedative property of this remedy? We are inclined to believe so. We were much pleased in finding out that MM. Trousseau and Maisonneuve are of the same opinion on this point. (See *Lancet*, March 30th, 1833.)

Now, to give a more satisfactory idea of our results on the employment of the *secale cornutum* in hæmorrhages and leucorrhœa, we put down all the different instances of both in the following

she was bled from the arm, and astringent medicines were ordered, which cured her very soon. This unfavourable result led us to adopt another method of practice in the following case (the second related to the Society), which succeeded very well, viz. to bleed first, then to give the secale.

The second was a stout woman who at her regular period was taken ill, but the bloody discharge was very profuse, and went on more or less for nine weeks. Had great pain at the lower part of the abdomen, and round her loins. Her pulse appeared weak. Five grains of the secale were ordered to be taken every second hour. Three days afterwards she was not better, and felt an increase of the pains after taking her powders. Her pulse was stronger. She stated having had a miscarriage about three months ago. She was bled, and directed to take the secale only three times a day, from which she felt worse, and was then suspended, and other means adopted.

The third case was that of Sarah Jones, æt. 33, married, admitted September 2nd, 1833.

Has had five children and miscarried twice, the second time five weeks ago, when she lost a great deal of blood. Three weeks afterwards, finding herself better, started for some place in the country, and came home to London, a distance of eighty miles. She was taken ill again on her journey, and lost a great deal of blood. She continued so more or less till August 31st. On the 1st of September the hæmorrhage became very violent, and she came to our dispensary the following day, and was under our care. She does not complain of any great pains but in her left iliac region and loins; her complexion is very pale, and there is great action of the heart and arteries, but her pulse is certainly weak and empty; her head feels heavy; her bowels are costive.

R. Pulv. secalis cornuti, ʒiij;
Divide in pulv. xxiv;
Pulv. i. 3a, q. h. sumend.;

viz. about viij. grains every three hours. A mixture with a drachm of carbonate of magnesia and two scruples of rhubarb in six ounces of water, was also given, a wineglassful of which to be taken every night, or night and morning, if her bowels were not open.

September 5th. She was sick, and vomited twice after taking the first powders, but felt only a sense of sickness afterwards at each time she took her powders. Had some giddiness, but the pains in her loins and side were relieved. The bloody discharge is reduced very much, and she states that it was so soon after having taken a few powders. Bowels regularly open. Soon after having taken a powder she feels "a general sense of weakness all over, from the head to the tips of her fingers and toes, as she could not stand; then she feels sick." Action of the heart and arteries less violent. Pulse more natural and soft. The mixture to be continued, and

the powders to be taken only every five hours.

September 12th. She is better; discharge great deal diminished, and less coloured. The powders continued to make her sick and weak. Continue with the powders.

16th. Feels very sick with her powders. Discharge a great deal increased; but she thinks *her time to be unwell is very near*. The secale was discontinued, and she was gradually doing well under the use of the following pills:

R. Ferri sulphatis, gr. i;
Extract. rhei, gr. iij;
M. f. pil. ter die sumend.

These pills were continued till the 7th of October, when she was discharged cured. Under these remedies the palpitation of the heart, and the excessive arterial action were reduced to their natural standard, and the patient got very soon better from that sense of general prostration, of which she was so much complaining before.

Although we put down this with the *unsuccessful cases*, still we thought that properly speaking, it should not have been considered entirely so, for the hæmorrhage increased in consequence of her having taken the secale when near mensturation. This was the reason which induced us to say in another place, that "only in two or three cases of menorrhagia, the loss of blood, &c., were remarkably increased by the action of the remedy."

The fourth unsuccessful case of menorrhagia is that of Mary Ann May, æt. 22, married, admitted the 4th of November, 1833. She had miscarried a short time ago, and was labouring under profuse menorrhagia for several days; was complaining of pains in the lower part of the abdomen and loins. She is a thin and delicate looking woman; her pulse appeared to us rather weak. Five grains of the secale cornutum were ordered to be taken every two or three hours.

Nov. 7th. She has been a great deal worse. The hæmorrhage increased very much, with spasmodic pains in the hypogastric region, and had giddiness, and pains along her thighs and legs. She took only six powders, and as soon as she left them off, the pains decreased. Her pulse was quick, and sharp, but empty. Her bowels are rather costive. The following mixture was ordered:

R. Magnesæ sulphatis ʒj;
Antimonii tartarisati, gr. ij;
Aque fontis, ʒviiij;
M. Cyath. parvul. i. bis terve die sumend.

21st. After the first glass of her medicine, she vomited several times, after which the hæmorrhage suddenly ceased, and she felt a great deal better; this was the reason she did not attend regularly. Now the hæmorrhage returns a little if she has to exert herself too

much. The secale cornutum was ordered again to be taken only two or three times a day.

25th. The hæmorrhage *entirely ceased* last Thursday evening (Nov. 21st) after having taken one of her powders, which she continued taking till to-day. She felt some pain in the lower part of the abdomen, but a great deal less than at the time she took them.*

In using the secale cornutum we preferred to give it in powder, as Dr. Spajrani did, being

also the most economical and convenient way in dispensary practice.

We seldom ordered it in more than five or six grain doses, more or less frequently repeated according to the violence of the case, or the peculiarity of the concomitant symptoms. We *purposely avoided* giving the secale intermixt with other medicine; but we were obliged sometimes to modify by other means the morbid condition of those parts or organs over which our remedy had to exert its powerful

VOL. IV.

cases, although it was only from our injudicious employment, and not from inefficacy of the remedy, that the hæmorrhage had not been arrested at first.

action; when at other times it was necessary to get clear of these irritating causes, which would have counteracted its beneficial influence; as, for example, the employment of purgatives when the bowels were costive. This, however, can never be an objection to our practice, as that *must* be always the case with the administration of any other remedies, which are given with a peculiar object. Although the criterion of the *post hoc, ergo propter hoc*, be not always correct, still we believe that in our profession, when violent symptoms are present, and we employ remedies of acknowledged activity, with the view of curing them, if we obtain a favourable and constant result for a sufficient number of times, we may begin to believe that criterion sufficiently correct. The weight of such a conclusion is moreover increased by the uniformity of results obtained by different individuals, and in different countries; therefore the following prospective view of the general results of the secale cornutum in hæmorrhages and leucorrhœa, will make a striking impression of the real efficacy of that remedy against those classes of diseases.

ON THE EFFECTS OF MAMMARY IRRITATION IN AMENORRHŒA.

BY CHARLES PATTERSON, M.D.

MARY REARDON, æt. 24, of moderately corpulent habit, was admitted into the Rathkeale Hospital on the 10th of August, 1832. She laboured under slight synochial fever, which soon yielded to venesection and purgatives. On the 19th hysterical symptoms presented themselves, with pain in the upper and outer part of the right side of the chest. For the relief of this a small sinapism was prescribed, which remained on half an hour. On the following morning the right breast was extremely painful, the pain being very different in character from that before experienced. On examination, the whole side of the chest was considerably swollen; there was slight diffused redness of the skin; and though the mamma was enlarged to four or five times its natural bulk, yet there was no circumscribed hardness nor any tendency to suppurative inflammation.

On the 21st, the right mamma and adjoining parts of the chest were found more swollen. The left mamma and side of the thorax were unaffected; the catamenia had appeared in considerable quantity. This discharge, which, as the patient stated, had been for two years and a half wholly suppressed, continued to flow for two days: it then began to decline,

and with it the tumefaction of the mamma gradually disappeared.

Catherine Power, æt. 19, applied to me on the 14th of September, 1832; she complained of headach, languor, loss of appetite, and listlessness. She stated, that about the middle of April, the menstrual discharge being then present, she incautiously exposed herself to damp and cold. The catamenia suddenly ceased, and had not since returned, and from that period she had been constantly subject to ill health. I ordered the clavicular half of the right mamma to be covered with a sinapism. It remained on for thirty minutes, and in six or seven hours after its removal the right breast was considerably swollen, hot, and painful. The next morning the enlargement of the mamma was very much increased, the tumefaction having extended to the clavicle and axilla of the irritated side. There was no hard circumscribed or prominent tumour, but a painful diffuse elastic distension of the mammary gland and surrounding cellular substance. On the evening of the day succeeding the application of the sinapism, the catamenia appeared, and continued for two or three days in moderate quantity, which greatly relieved the headach and other distressing symptoms, and in a week her health was restored.

In both these cases cold evaporating lotions and gentle saline aperients were employed to moderate the local phlogistic engorgement. Both patients have since continued to menstruate regularly.

From the facility with which the menstrual flux was induced in these cases, it would seem that the beneficial effects in amenorrhœa, lately observed to arise from the long-continued daily application of one or two leeches to the breast, were entirely owing to the great irritation which the leech-bites had eventually produced in these organs. The abstraction of blood by leeches from the mamma had not (according to the reports of the cases in which they were employed) the least perceptible influence over the uterine functions, until pain, heat, and excessive tumefaction of the breasts, had been first developed. Phlogistic engorgement of the mammae being the essential step in the movement, which, in these instances, determined the flow of the catamenial discharge, it must be obvious that, for the pro-

duction of the necessary irritation to effect that engorgement, the simple application of a sinapism would have been, in every respect, infinitely preferable to the tedious and troublesome process of the daily repetition of leeching.

But it must not be supposed that mammary irritation is applicable to every form of amenorrhœa. I have found it fail in some cases.

Mary Fitzgibbon, æt. 21, of spare habit, affected with headach and irregular dyspeptic symptoms. The headach permanent, occasionally aggravated; countenance and tongue chlorotic; mammae undeveloped. The menses had been scanty and irregular from the 16th to the 19th year of her age, but had been totally suppressed during the last two years. No apparent organic impediment. A sinapism was first applied to one breast, and afterwards to both breasts at the same time; but, though they produced their ordinary effects, yet the enlargement of the mammae was very trifling, and there was no consequent uterine action.—*Dub. Journ. of Med. and Chem. Science.*

CALCULOUS AFFECTIONS IN EGYPT.

M. CLOT BEY states, that calculous disorders are very common in Egypt; he has operated on forty cases since his residence in that country. The affection is a rare one among the Nubians and Abyssinians. There are two methods of performing the operation; one is the perineo-vesical, the other the recto-vesical.

In both two fingers of the left hand are carried deep into the rectum, to grasp and confine the stone, and to make it protrude as much as possible; a deep incision is then made directly upon it, and the fingers of the right hand are generally used as forceps to withdraw it. Very few patients die of the operation, although most of them labour afterwards under incontinence of urine.

The recto-vesical operation is the one generally performed; it is easy of execution, as a large stone may be most conveniently withdrawn, and the risk of hæmorrhage is less than in any other.

Out of the thirty-eight cases operated on by M. Clot, eleven were cured from the seventh to the tenth day after the operation; sixteen from the eleventh to the twentieth; eight from the twenty-second to the thirtieth; four

from the thirty-second to the fortieth; and one from the fortieth to the fiftieth; two only died, and three were discharged with vesico-rectal fistulae.

M. Clot unites with Baron Larrey in ascribing the great success of the operation to the fine climate of Egypt, which is favourable to the healing of wounds, and to the constitution and temperament of the people not being easily irritated or excited. In five of the above cases M. Clot performed the recto-vesical operation; in three of these the fistulae remained uncured. He admits that the operation is exceedingly easy of execution, and that any large calculi may be conveniently extracted, but he has abandoned it for the rapheo-vesical method proposed by Vacca, and which he has performed eleven times; the stone is extracted at the most roomy part of the perineum; no important blood vessel is exposed to the knife, and the rectum can with difficulty be wounded. The only serious objection which has been urged against it, is the danger of wounding the seminal tubes, but only one of these can be wounded, and the other remains safe and perfect.—*Annales de la Médecine.*

Gastrotomy in extra-uterine pregnancy.—

A negress in Brazil expected every day to be delivered; labour, however, never came on regularly, and soon all pains left her entirely. The swelling of the abdomen remained as great as ever, and her health soon began to decline. In the course of two years an abscess formed about the umbilicus, and some foetal bones were discharged. Dr. Benit then determined to open the abdomen by an incision of from three to four inches in length, and using his fingers as forceps, he extracted the putrid remains of a decayed foetus. The edges of the wound were brought into contact, and the patient confined to a rigorous antiphlogistic treatment for two months, and she ultimately quite regained her health.—*Ibid.*

Reports of Societies.

HUNTERIAN SOCIETY.

Wednesday, Nov. 27, 1833.

C. ASTON KEY, Esq., President, in the Chair.

THE subject of syphilis in some of its anomalous forms, was continued.

q q 2

Mr. Key remarked, in reference to the minutes of the last meeting, that it was common for women to have sores near the orifice of the vagina, in the mucous membrane, without their being conscious of it. If there were merely a discharge from the follicles it imparted gonorrhoea, but if there were ulceration of the follicles it produced chancre. He adverted to a cutaneous affection, *rupia*, usually considered syphilitic; but he had met with four instances in which he could detect no syphilitic taint. This he regarded as cachectic *rupia*. The patients became well by an allowance of porter, and by taking capsicum and quinine, or nitric acid and sarsa.

Mr. Bevan adduced an instance of *rupia* which had evidently arisen from syphilis. The glans penis had sloughed.

Mr. Roberts related a case of *rupia*, of syphilitic origin, in which the red oxide of mercury, with sarsa, proved speedily beneficial.

Dr. Whiting reported the case of a man on whose skin appeared syphilitic lepra. Four months before, he had contracted chancre, and the sore healed of itself, but now bubo and eruption occurred. The Doctor observed that the sore might have been primary venereal disease, or a syphilitic disease capable of contaminating the constitution.

Mr. Hingerton had no doubt that the syphilitic sore will sometimes get well of itself, or under simple treatment. A man consulted him about a sore of whose nature he was doubtful. He sent him to an eminent surgeon who pronounced it not venereal, and prescribed accordingly. The sore healed, but three months afterwards secondary symptoms arose. He directed attention also to the failure of power and fever which occasionally precede the breaking out of secondary symptoms in cachectic habit.

Mr. Key thought it saying too much that the febrile excitement arose from the venereal affection. He admitted, however, that there sometimes is a disturbance in the system, and that pulmonary affections occasionally come on under these circumstances. He was so accustomed to observe excitement accompanying some forms of secondary symptoms, that for ten days he often employs antimony and sarsa. If mercury be given in this state, it salivates too quickly.

Dr. Babington adduced the testimony of

army surgeons that in most cases there is no appreciable disturbance.

Mr. Key adverted to the effects of diet in the treatment of syphilis in the army. The common soldiers have their diet prescribed, and they cannot avoid conformity to it, and the treatment of the disease in them is very easy; but with respect to the officers it is not so easily cured. He believed no disease is so much modified by habit, as the one in question. In reply to a question, whether the secretion of the male can impart the disease, he expressed his persuasion that in most of the obscure cases abrasion took place. There had been a chancre which had healed, but the skin remained thickened, and from coitus the part becomes abraded. Ulceration then occurs in one of the mucous follicles of the vagina. He had seen eight or ten instances of this kind in young married women.

Mr. Hooper reminded the President that in a case related at the preceding meeting there was no abrasion of the part in the male, nor could any sore be detected in the female.

Dr. Whiting considered it well to look at the various arguments in reference to cases in which something is produced independently of sores. It is acknowledged, he said, that the child in utero can have the disease, and he presumed it must be either through the medium of the circulation in the mother, or by means of her nervous system. If so propagated, he asked, where is the improbability of its being communicated by the secretions of the male. He admitted that positive proof could scarcely be obtained, but he believed that the disease can be communicated without sores. He considered the disease, in general, as local, and not dependent on constitutional irritation. The fever which sometimes arises he would rather regard as a sequence than a cause, as the same as symptomatic fever from other causes. If you have inflammation or fever, the disease will be more obstinate, you have more morbid action to combat. You must, therefore, get rid of the inflammation and fever, and then your specific or agent will be more effective. He considered this remark applicable to all specific diseases, all the exanthemata.

Mr. Hooper admitted that the principle was good, but thought it often a puzzle how to act upon it. Though changing the subject, he could best elucidate his meaning by referring

to a disease now somewhat prevalent in his neighbourhood in a very malignant form, scarlatina. The disease was set up with inflammation, the throat became highly inflamed, and had depletive measures been resorted to, he believed the result would have been worse than it was. In one family he had lost three sisters. He did not see the eldest till three days after the onset. The pulse was 130 or 140; the strength prostrate; the throat tending to lividness; and there was ulceration round the velum palati. The third sister, who had previously been an invalid, was seized at two o'clock in the afternoon, and in the evening was a corpse. There was pallidness and diarrhoea, but no soreness of throat, so that there was no proof of the existence of scarlet fever. Mr. Hooper believed, however, that she died of some cause which gave malignancy to the disease prevailing in the family. In the third sister the affection of the throat was preceded by vomiting and purging. The chief remedy employed had been ammonia. Four other children in the family were affected, and were treated in the same way.

Dr. Ashwell advocated, the efficacy of ammonia in this exanthem, and Dr. Babington that of the antiphlogistic method of treatment.

The President suggested that as the time for adjournment had now arrived, he thought the subject was of sufficient importance to be resumed at the next meeting, Dec. 11th.

WESTMINSTER MEDICAL SOCIETY.

Saturday, November 30, 1833.

DR. GREGORY in the Chair.

Medical Reform.—Tribute paid to the late Medical Officers of the General Dispensary, Aldersgate-street.

THE minutes of the last meeting were read and confirmed.

Dr. Gregory then read a recommendation made by a large number of the oldest members of the Society, that the late Medical Officers of the Aldersgate-street Dispensary be elected Honorary Members of the Society. The proposition was put to the meeting and unanimously carried.

Mr. King then addressed the Society at great length on the great necessity of medical reform. He contended that the preliminary education of those intended for the profession was too much neglected in this country, while

in France and other parts of the continent of Europe a good knowledge of classics and general information was required. It was rightly considered, that the mind of a medical practitioner ought to be as enlightened as possible. The term of apprenticeship is too long, a year was sufficient, and the remainder of the time should be spent in attending lectures and hospitals. In his opinion, four or six years ought to be spent in this way, and clinical medicine was not sufficiently studied either at home or abroad. One examination was not a sufficient test of the competency of a surgeon, even if it was continued from morning until night. In France no one could become a doctor of medicine or surgery without a good general education, which, if approved of, entitled the candidate to the title of bachelor of letters. There were six medical examinations on all the branches of medicine, besides writing and defending a thesis*. Every practitioner should be qualified in medicine and surgery, as there was no arbitrary distinction in nature. There should be one Faculty of Medicine.

Mr. Costello rose to order, and said that Mr. King was discussing topics which had been disposed of at the last meeting.

Mr. King concluded by moving the fourth resolution, relative to the abuses in the College of Surgeons, which appeared in our last.

Mr. Greenwood seconded this resolution; and said that the Examiners and Council had no object in view but dividing emoluments among themselves. They were self-elected, irresponsible, and had no connexion or community of feeling with the members of the college at large. They refused to recognise some of the ablest lecturers, as Carpue, Bennett, &c., as many of them were lecturers themselves, and most of them hospital surgeons, and they combined to exact large fees from students, for the purpose of filling their own pockets. They impeded the progress of science, and they refused to recognise provincial lecturers as long as they could.

Mr. Holt observed, that, according to the Parliamentary Report, the fees to examiners were £4754.

Dr. Somerville supported the argument in favour of a better general and professional education. The College had not applied to

* This number of examinations are required in Edinburgh and all the Universities.

Parliament to prevent quackery and the murder of his Majesty's subjects. He would mention a humiliating fact, and it was this, that the Secretary of State for the Colonies had many appointments at his disposal at the present moment, and he felt convinced that the College diploma was not a sufficient test of knowledge, and therefore he required regular surgeons to be re-examined by the Director General of the Army. There should be no sordid gain in conferring medical honours. In the by-laws of the College there was the narrow rule, that Fellows, not members of the College of Physicians, were admissible to the Museum and Library.

Mr. Lavis remarked, that the College neglected the interests of the members at large, did not apply to the legislature to give remuneration for attendance on hospitals, prisons, workhouses, &c. One of the Council told a patient of his, that his demand for setting a fracture, and attending for several weeks, which was only two guineas, was too much.

Mr. Walker said, that the system pursued by the College was the most injurious to science and humanity. The sole object of the managers was, to bring grain to their own mill; they refused to admit those who had attended foreign lectures; and they kept hospital appointments among themselves and their connexions.

Mr. Chinnock proposed the next resolution relating to the Apothecaries' Company. He admitted that this Society had done a vast deal of good; their examination was excellent; but it was monstrous that they should have the power to examine the goods of fellow-tradesmen and inflict fines. They had no power over chemists and druggists; and these individuals, without any medical education, not only compounded medicines as apothecaries, but practised medicine and surgery. The Company of Apothecaries never prosecuted them, but reserved the terrors of the law for those studying medicine, whose ultimate object was, to be legally qualified practitioners. The general practitioner—the public's doctor—had no protection, nor was he allowed to lecture, however competent he might be. They had no stimulus for exertion. The churchman saw a bishopric in perspective; the lawyers, the woollack; but the general practitioners, no object of ambition. They were the physicians, surgeons, and obstetri-

cians of the multitude, and as useful to the public as any grade in the profession.

Dr. Blicke seconded the resolution, and mentioned many acts of oppression on the part of the Company of Apothecaries. These persons were totally unfit to govern so respectable a body as the general practitioners of England and Wales.

Dr. Epps rose to propose a verbal amendment to the same purport, and fully agreed with the sentiments of the mover and seconder of the resolution. He was under no compliment to the Company of Apothecaries, as they refused to recognise his lectures on the Practice of Medicine until he became a member of the College of Physicians. Nevertheless, he should do them justice; they had greatly improved the education of students within the last few years. But, as a trading body, it was unjust that they should have the power to fine their fellow-tradesmen, or to preside over the science of pharmacy. Had the College of Physicians done their duty, we should be all physicians, and the Apothecaries' Hall would be confined to pharmacy alone. He could not agree with Mr. Chinnock, that, as tradesmen, they were unfit to govern general practitioners; because all general practitioners who sent in medicines, and charged for them, were tradesmen; and men of science ought to be remunerated for their skill and attention. Dr. Epps then proposed,—“That the exalted state of the General Practitioners was such as to place them superior to the Company of Apothecaries, and that they should be governed by a scientific body.”

Dr. Johnson seconded the amendment.

Mr. Hunt then rose to propose the next resolution, but

Dr. Johnson moved an adjournment, on account of the importance of the subject and the lateness of the hour.—Adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, December 2, 1833.

WILLIAM KINGDON, Esq. in the Chair.

Secale Cornutum in Gonorrhœa and Leucorrhœa—Leucorrhœa in Children—Poisoning by Morison's Pills.

THE second part of Dr. Negri's paper was read, which will be found in a preceding page.

A gentleman observed that the evidence

afforded by the paper was not satisfactory to him, as other remedies had been used, and change of diet or circumstances during the interval between the exhibition of the doses might account for the improvement in the diseases. He had used tartarised antimony and muriated tincture of iron in nauseating doses in gonorrhœa and gleet with benefit, and the ergot produced nausea and vomiting in one of the cases.

Mr. Procter said, that after the candid and impartial narration of the cases read before the Society, he was surprised at the observations just made; but, for his own part, he thought the paper one of great importance. There were no cases more annoying or tedious than gleet or leucorrhœa; and in these diseases most of the remedies in use fail every day. He, for one, should certainly try the *secale cornutum*, as recommended in Dr. Negri's excellent paper.

Dr. Burne could bear testimony to the efficacy of *secale cornutum* in uterine hæmorrhage, after abortion and labour among poor women. In such cases he had found the sulph. sodæ ʒj. and acid. sulph. dil. ℥x. given three times a day generally effectual. In leucorrhœa, he found a lotion, not an injection, of liquor. ammon. fort., properly diluted, almost invariably efficacious. Leucorrhœa was extremely common among dispensary patients,—it occurred in three cases out of four, and he was of opinion that constipation of the bowels was one of the exciting causes of it.

Dr. Shearman considered the paper before the Society one of much interest; and he related two cases of abortion, one at the fifth and the other at the third month, accompanied by uterine hæmorrhage, in which the last affection was arrested by the remedy in question. This case occurred some years since, when the remedy was first introduced into practice. He thought that the observations of Dr. Burne were of great value.

Mr. Birt inquired in what doses the remedy was administered.

Dr. Shearman replied, in doses of ten grains every three or four hours.

Mr. Kingdon related two cases, one of early abortion, the other of leucorrhœa, both of which were cured by the ergot of rye. He ordered it in much smaller doses,—ʒj. in Oj. of water, and ʒj. of this infusion with a tonic mixture of cascarrilla.

Mr. Dendy remarked that the observations made by Dr. Burne were worthy of great consideration, as too little attention had been paid to the exciting causes of leucorrhœa. He had lately under his care, thirteen or fourteen cases of genital discharges in children, some of which were leucorrhœal, and others were similar to that produced by specific virus. He thought that worms or intestinal irritation were exciting causes, and used ordinary means in these cases. Twelve got well; the remaining four were ordered the *secale cornutum*, as recommended by Dr. Negri and Dr. Ryan. He did not think, however, that they had described with sufficient minuteness the pathology of the diseases alluded to in both of the papers read before the Society.

Mr. Kingdon remarked that Dr. Negri did not profess to describe the diseases mentioned in his papers, but the efficacy of the ergot of rye in cases of these maladies.

Mr. Clifton observed that the papers were worthy of serious consideration, as they contained much valuable information on the efficacy of the *secale cornutum*. He thought that the remedy ought to be tried in all cases in which it was recommended, especially in early abortion; but great caution would be necessary, lest the medicine might excite uterine contraction, and produce abortion.

Dr. Ryan wished to make a few remarks on the subject before the Society, as his friend Dr. Negri had mentioned some of his cases. He bore his fullest testimony to every fact with which his name was connected in the papers; and would assure the Society, that if the members employed the remedies in a genuine state, its beneficial results in all the cases related would be obvious. A great diversity of opinion existed with regard to the power of this medicine; but this arose from the want of any correct history of it in the English works on *Materia Medica*. The ergot should be good, and preserved in closely stopped bottles, so that exposure to air and moisture do not take place. It may be given in powder or tincture, and the latter, which he employed, is composed of ʒij. to the pint of proof spirit; the maximum dose was ʒj. He had known a gentleman give ʒj. of the ergot without any effect, but he had kept it in paper in an open drawer. He, Dr. Ryan, gave him ʒj.; which he had about him, and afterwards learned that his friend considered

the ergot one of the most powerful remedies in use. He thought the effects of the ergot in small doses different from the quantity given to induce labour, like alterative and scruple doses of calomel; and that there was no danger of causing abortion with small doses.

Mr. Headland observed, that in his opinion practitioners ought to be cautious in using this remedy on a large scale, as, like all other kinds of deteriorated grain, it might produce very bad effects.

Mr. Kingdon concurred with the last speaker, and feared that many of the medicines now in constant use were open to the same objection.

Mr. Clifton said that, in his opinion, the failure of the secale cornutum was to be ascribed to its not being kept properly; and thought that if given largely it might cause bad effects. He saw a child a few days ago, that was nearly killed by Morison's vegetable pills, which produced all the symptoms of narcotic poisoning.

The Society then adjourned.

London Medical & Surgical Journal

Saturday, December 7, 1833.

MEDICAL REFORM IN FRANCE.

Omnis Gallia est divisa.

In the state of transition through which the medical institutions of this kingdom are at present passing; when we consider the many causes which have insensibly led to their degradation, and the very little which has been attempted for their systematic improvement, it is not uninteresting to turn our eyes to the revolutions of the republic of medicine among our active neighbours, whose experiments have gone the round of every social institution. The very subject, besides, is of a cosmical character: the lawyer confines himself to the civil law of his country, the divine is restricted by the ceremonials of the religion he professes:—but the *Medicus*, whether at home or abroad, pursues a science of universal application; and there is nothing in the manner and extent of his

education, in the ranks into which his profession should be divided, or the ethics which should regulate his practice, which is not as applicable to one great civilised community as to another. Our readers will not, therefore, be surprised to find, that the discussions upon medical reform, which at present occupy the French Schools, are the very counterparts of those in which we are now engaged; and we invite their serious attention to the medical reforms contemplated in France, an abstract of which we propose to lay before them.

The French revolution, which levelled every political fabric, from the throne to the altar, led to the suppression of the Universities, and put an end to all public instruction. The general conflagration, says an able writer, consumed an edifice, which it would have been far better to repair than to pull down*. But the task of rebuilding was undertaken with quite as much energy as that of destroying: and the spirit of *organisation* soon extended itself to the medical institutions. It is unnecessary to enter into a particular account of the new system, and the changes it underwent, under successive governments. We have, on a former occasion, given an epitome of the French code of medicine, and the more important points will come under review in the sequel.

The arrangement, however, whether emanating from those who believed in perfectibility of man and his institutions, and who had a *carte-blanc* for their schemes, or from the omnipotence of Bonaparte, were far from satisfactory to the profession and the public: and, in consequence, in 1829, the Minister of

* L'incendie général consuma un édifice qu'il aurait mieux valu sans doute réparer qu'abattre.—*Lacroix sur l'Enseignement*, p. 66.

the Interior addressed a series of questions to the Academy of Medicine, upon the re-organisation of the profession. The Academy immediately appointed a committee to report their opinions. But, it seems, the apparent resolution of the government to introduce its agents into the projected medical councils, was so unpalatable to the profession, that the labours of the committee went on but slowly, till they were at length interrupted by the éclat of the last revolution. The whole attention of medical men was soon after absorbed by the spread of the cholera; and it was not till last July, that this important subject was resumed.

The late revolution gave a considerable impulse to the cause of public education in that country. The duty of watching over public instruction is now intrusted to a special cabinet minister, and this office has fallen to one of the most enlightened men in France.

In July last, M. Guizot renewed the application to the Academy, and claimed its long expected answer. In October last, M. Double read to the Academy the report of the committee, which contains a long and very able examination of the imperfections in the present medical institutions, and the alterations of the law which the committee unanimously recommend.

Of the vices of the late government of France, its monopoly of education was among the most offensive.—The liberty of teaching is one of the watch-words of the new charter. The committee, therefore, dwell with complacency upon the absurdity of the monopoly of teaching, especially in medicine. There is no science, whose advancement is so inseparably connected with its tuition as medicine. In it the teachers are, or ought to be, the most extensive practitioners. We have indeed nothing to apprehend, nor have the

French, under their present government, in the interposition of politics in medical affairs. But we may reasonably allow our neighbours to exult in their new emancipation and independence.

By far the most important discussion in the report, both as regards the reform of the French school, and its intimate connexion with the position of general practitioners in this country, is that which relates to that peculiar class of practitioners, the Officers of Health. The report demands the suppression of this class, and, in consequence, of the medical juries, by whom they were admitted.

It insists upon the suppression of secret remedies, or, in the vernacular, *quack medicines*, “hitherto the incurable wound of medicine;”—this head we propose to transfer into the English code, *mutatis mutandis*.

Its next subject is the abuses which have insinuated themselves into the tuition and practice of the healing art, and the effect to be given to foreign degrees; and, finally, the abuses which have crept into the practice of pharmacy, or the trade of an apothecary, occupies its serious attention. In this latter branch, it has resolved that the business of an apothecary should be precisely and absolutely isolated from the sale of drugs, or the business of a druggist.

It will be seen from this sketch of the report, how home to our business are the inquiries now mooted among our enlightened neighbours. And, although there are more difficulties in the way of a thorough medical reform among us, than in France,—arising partly from the complicated state of our medical institutions, and their clashing privileges, and partly from the vast respect, which is too often shown in this country to private interests and individual prejudices;—still, we look

forward with considerable satisfaction to the effect upon our public men, of an example of such a complete reform, as is likely to be accomplished in the medical profession of France.

The first question which is addressed to the Academy relates to the possibility of removing, without inconvenience, the existence of two orders of medical men. In examining this question, the Committee state the different qualifications of the two orders already found amongst them.—A diploma from the Faculty of Lettres; another from the Faculty of Sciences; four years' *inscriptions*, taken in the Faculty of Medicine; five examinations: the first in Natural History, Pharmacy, Physics, and Medical Chemistry, at the end of the first year; the second, Anatomy and Physiology, at the end of the second year; the third, on Medical and Surgical Pathology; the fourth on Hygiene, Medical Jurisprudence, *Materia Medica*, and Practice of Physic; the fifth, on Internal Clinique and Midwifery, these latter three after the fourth year; a thesis, and expenses of 1100 francs (less than 50*l.*)—these are the obligations that must be fulfilled for the degree of Doctor in Medicine or in Surgery. This degree confers the right of practice to its full extent. The requisites of the inferior class are stated to be preliminary studies, none, or insignificant; three years' study in a faculty or a secondary school, which may be replaced by six years' attendance in an hospital, or studies with a doctor; three examinations, most frequently illusory; an outlay of between 250 and 300 francs (about 9*l.* and 10*l.*)—such are the demands upon the inferior order of practitioners. Their range is limited to a particular department; and all capital cases of surgery are, *by law*, excluded from their practice. All infractions of

the law are punishable by action; but doctors recoil from the anxiety and scandal of a law-suit; and the officers of health enjoy a practical immunity from the letter of the law.

The Committee then take a general view of the profession in foreign kingdoms, and observe, that in England the apothecaries have the right of practising and prescribing the remedies they propose; that they form, truly, a class of practitioners inferior to the physicians. In some respects the analogy is complete. The apothecaries' right to *prescribe*, "without taking or demanding any fee for their advice," was recognised more than a century ago. It is strange how such a proposition could have ever been doubted. Their right to charge a fee has been admitted in a late case, of which the authority is questioned. That there is between them and the regularly educated physician a war, ruinous to the interests of science, and injurious to the public, is also true.

That there should be no difference in the degrees of qualification required from medical practitioners—no privilege of ignorance; that the science should be accessible to all, but that all should be obliged to cultivate equally the science; that the health of the poor is as valuable to the state, as the repose of the wealthy; are propositions too plain to admit of being directly denied. It is well observed by the report, "mediocrity will never be wanting; it is a law of humanity, which the legislature cannot remedy;—it is its duty to stipulate for society all the guarantees that are at once possible and necessary." What would our French brethren say of the contemptuous privilege claimed by the Fellows of our College of Physicians! They set up no right to superior medical attainments—these are hardly bought by years of unremitting

study. But, forsooth, they have been at the Universities,—they are classics, no doubt; science is not beyond them; and, *proh pudor*, they carry into society a collegiate reputation for morality!

After reflecting upon the increased importance, which the medical profession will possess, as society advances in improvement, the report proceeds to consider some objections to the abolishment of the Officers of Health, from the necessities and poverty of some districts of the country; and recommends the appointment in such places of doctors on the footing of our parish surgeons, or the surgeons of the county infirmaries in Ireland. Besides, to induce medical practitioners to spread over the country, it is proposed, that doctors and apothecaries hereafter admitted, shall be required to pay, on establishing themselves, a fee for the right of practising, which shall vary according to the department and population of the commune, in which they shall fix their residence:—this fee, with the expense of inscriptions, not to exceed the sum a degree at present costs; and subject to this arrangement, all probatory acts to be gratuitous; upon a change of abode, the surplus to be paid.

To meet the increased demand for medical instruction, the report proposes, in addition to the three Faculties already existing in Paris, Strasbourg, and Montpellier, the establishment of three additional, one at Lyons, one at Rennes, or Nantes, and one at Bourdeaux, or Toulouse. And to render the examinations more strict, it is proposed that the examiners shall not be confined to the members of the Faculties, but that one-third shall be taken from the medical men of the city and neighbourhood of the Faculty.

To carry these measures into effect, to watch over the exclusive rights of the doctors, to enforce the law against quacks,

and, above all, to regulate the morals of the profession, guard the purity of its practice, and diffuse a spirit of social fellowship among its members, the committee rely upon the establishment of *departmental medical councils* under the sanction of law.

To this branch of their enquiries the committee have paid great attention. We shall recur to this subject, and the proposed amendments in the practice of pharmacy upon a future occasion;.

WESTMINSTER MEDICAL SOCIETY.— REFORM DISCUSSION.

“*Tantæne animis cælestibus iræ?*”

ONE of our contemporaries, known to our readers by the soubriquet “Chlorosis,” finds an apt similitude to the Westminster Medical Society and its numerous members, in the trades’ union and combinations against taxes! It seems, then, the master tradesmen are by no means satisfied at the appearance of unity and combination among their menials. We are rejoiced at the information;—the nausea proves the medicine is beginning to work.

At the discussion on last Saturday, Dr. Epps moved an amendment to the 5th original resolution, to the effect that it was unfit that the Apothecaries’ Trading Company should continue to govern the general practitioners in their present exalted state. The amendment is certainly an improvement upon the grammar of the original resolution, and does not much affect its spirit. To our apprehensions, the Doctor is of opinion,—we infer from the words of this resolution,—that the general practitioners should themselves cease to trade: but we should like to see this position fairly and explicitly stated, to leave no room for *doubt*, whether more is meant than meets the ear. The discussion is adjourned.

MEETING OF THE APOTHECARIES
OF IRELAND.

A NUMEROUS and highly respectable meeting of the Apothecaries of Ireland was held in Dublin on Tuesday week, at which Mr. Donovan presided. Several provincial apothecaries were present. It was resolved that a petition should be sent to both houses of Parliament against the act lately proposed, and asking that physicians and surgeons now in practice should not be allowed to practise pharmacy without a previous examination. A warm discussion then took place on the propriety of the meeting uniting with the Dublin Apothecaries' Hall, the result of which was, after an eloquent speech by Mr. Kane in favour of the union, that such a union should not take place.

We highly approve of this decision, and think that the National Association of Apothecaries were quite right in refusing to coalesce with the [monopolists in Mary-street. The time is at hand when the medical world must be properly governed, and all corporations perfectly purified.

French Hospital Reports.

HOTEL DIEU.

Internal Strangulation cured by the em-dermic use of Croton Oil.—Penjat, a groom, æt. 28, and of a lymphatic temperament, had been afflicted with inguinal hernia of the right side for four years. The hernial tumour was small, and could always be easily reduced, and being frequently obliged to ride out, he constantly wore a supporting bandage. One morning on rising, he re-applied the bandage as usual, and in the course of the same day he was suddenly seized with nausea and severe colicky pains of the bowels, which increased for several days; leeches and fomentations were applied to the surface of the abdomen, and he was placed repeatedly in the warm bath. When admitted into the Hôtel Dieu, he had severe pains over the whole abdominal region, which were much increased on pressure, especially around the umbilicus, and severe nausea and vomiting. On examination, no tumour could be detected in the abdomen or inguinal region. The in-

ferior orifice of the inguinal canal was sufficiently narrowed, which proved that the hernia was for the present reduced. There was headach, agitation, and anxiety; the tongue was moist, and covered with a yellow fur, and no thirst; he had not had any evacuation of gas or fæces for four days.

M. Sanson remarking no symptom that warranted the performance of an operation, decided on employing the antiphlogistic treatment. Thirty leeches, with emollient fomentations, were applied to the abdomen, and he was afterwards placed in the bath. His symptoms were slightly alleviated by this method of treatment, but they soon returned again. The same remedies, with the addition of a blister on the upper part of each thigh, were continued without any relief being obtained. Five drops of croton oil were ordered to be applied to each blistered surface, and in the course of a short time there came on free and frequent evacuations from the bowels; the pains were immediately relieved after the first alvine discharge, the belly became soft, but the pulse still remained frequent. He passed a good night, and on the following morning two purgative injections were administered to prevent any attack of inflammation, and the next day he went out quite well.—*Lanc. Fran.*

Rhinoplastic operation.—A young man consulted M. Dupuytren some time ago, respecting an eating ulcer, which had already destroyed a considerable portion of the point and septum of the nose. Under mild treatment the sore was healed, but a disgusting deformity remained in consequence of the loss of substance.

M. D. resolved to attempt its restoration; and in this case he cut the flap from the upper lip, which was unusually thick and long. Having accurately marked out the dimensions required, an incision was made through one half of the thickness of the lip, and the flap was then dissected or sliced off, the inner surface or face of the lip being left uninjured. The flap was now "retourné" by twisting its pellicle from right to left, and secured to the raw edges of the nose by hair-pins and the twisted suture. On the sixth day the pins were removed from the lip, and on the ninth from the nose; the flap had united to the septum and point of the nose.

The part where the pedicle of the flap was twisted round formed a disagreeable protuberance, which after a time was divided, and all the irregularities pared carefully away. The cure ultimately was a very satisfactory one.—*Journ. Hebdom.*

Portuguese Hospital Reports.

(Continued from page 446.)

Gun-shot wound of the Abdomen.

Sept. 28th. As some Miguelite soldiers were firing on their enemies, who were retreating across the Douro, after a sortie to destroy a battery on the opposite side (the south) a musket ball wounded Wm. Williams, captain's steward of H.M.S. Childers, a man 26 years old, of regular habits, and robust health. The ball entered his back to the left of the spine, and about two inches and a half from it, fracturing the eleventh rib, and making its exit through the cartilages of the false ribs, about one third the distance from the distance from the sternum to the spine. But little hæmorrhage followed the infliction of the wound; he, however, became faint and pale; pulse feeble; skin cold; countenance expressive of great alarm; complained of a sense of constriction in the region of his stomach. From the exit of the ball I extracted a piece of his flannel. The wound emitted some foetid odour, and soon after there oozed thence the fæcal matter. Ordered to be kept perfectly quiet, and to have neither food nor drink.

29th. Eight, A.M. Was very restless until five this morning, when a grain of opium which was given him, had the effect of easing the spasms and vomiting that had been distressing him throughout the night; is very pale, cold, and weak; pulse feeble and frequent; abdomen tumid; the exit of the ball continues to discharge fæces. The exit wound to be frequently dressed simply; quietude and abstinence to be persisted in.

Nine, P.M. His pulse getting up this afternoon, he was bled until he became faint; blood very buffed and cupped; has been very weak since venesection; pulse feeble and 120; abdomen remains tumid, and is a little painful on pressure. He lies on his back with thighs bent on the belly, and has been in the same posture since he received the wound. Fæcal matter continues to ooze from

the tract of the ball. The same rigid abstinence to be persisted in, and to have a common enema at *h. e.*

30th. Ten, A.M. Has been rapidly sinking since three this morning; at seven he became very restless and delirious, and at nine, A.M. he expired, 44 hours after he received his mortal wound.

Autopsy, two hours after death.—*External appearances.*—Abdomen is much distended, a few hours before death a great quantity of fæces was discharged through the tract of the ball, and per anum.

Internal appearances.—The ball having fractured the eleventh rib, penetrated through the inferior margin of the spleen, passed through the colon, at the angle of its transverse and descending portions, and made its exit where I have before described. The intestines in the neighbourhood of the wounded colon were highly vascular, and in the cavity of the belly was a great quantity of extravasated blood, very dark in colour. A good deal of fæces had been extravasated, but its diffusion among the intestines was guarded against by the adhesions the adjacent parts had contracted. It was, in short, contained in a kind of sac, the open mouth of which was the end of the tract of the ball.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Psoriasis Diffusa.

ELIZA SMITH was admitted under the care of Mr. Lawrence. Her entire body was covered with large patches of irregular dimensions, and of a red shining colour. In some parts the patches have become confluent. The disease is attended with a sensation of heat, and she complains of great pain all over her body; her face and head are completely free from the disease. She complains of very great itching, more particularly at night time. Her general health is very good, and her bowels very regular.

She has been ordered to take three minims of liquor arsenicalis three times a day.

WESTMINSTER HOSPITAL.

Calculus in the Bladder.—*Lithotripsy by Baron Heurteoup.*

W. R., a native of Norfolk, about sixty years of age, and of extremely healthy appearance,

was admitted on the 6th Nov. under the care of Mr. White, labouring under all the symptoms of stone in the bladder. He has been labouring under the symptoms of the disease during the last two years, which latterly became exceedingly distressing, and obliged him to come up to London in hopes of gaining some relief in one of the metropolitan hospitals.

Mr. White, with the concurrence of the patient, requested Baron Heurteloup to sound him, and if necessary to perform lithotripsy. The Baron accordingly sounded the patient, and the stone (about an inch in diameter) was distinctly felt. The Baron then proposed his operation, to which the patient consented.

On Saturday last, Nov. 23rd, in the presence of a large number of medical men and students, Baron Heurteloup proceeded to operate. The patient being placed on his back on the operator's rectangular bed, the Baron injected the bladder. The stone was then readily seized, and the hammer being applied to the external portion of the instrument, it was speedily pulverised. The patient then voided the contents of his bladder with force into a basin, which being allowed to remain quiet for some time, deposited a large quantity of pulverised stone at the bottom of the vessel.

During the operation, the patient appeared to suffer little or no pain, and on going out of the operating theatre, turned round to thank Baron Heurteloup.

The Baron then addressed the gentlemen present, through an interpreter, and at the request of Mr. Guthrie explained the plan of the instruments, and went through each portion of the operation with minuteness and clearness.

His observations were very similar those reported in No. 90 of this Journal, and need not be inserted here.

The venerable Mr. Lynn, who previous to the operation seemed to be rather sceptical in his opinion of the advantages of the lithotripsy, expressed his very great satisfaction at the manner in which the operation was performed. It was his first time of witnessing the operation, and he appeared highly pleased with it.

The patient on being placed in bed conversed most cheefully with the surgeons, and

evidently appeared quite astonished at the trifling nature of the operation.

We shall report the treatment and the success of the operation in the next number of the Journal.

Inflamed Bursæ of the Knee.

In reference to a case of diseased bursæ of the knee at present in the hospital, Mr. White remarked, "this, gentlemen, is inflammation of the bursæ, and is very frequent in servant women, who are obliged to go on their knees in their occupation of scouring floors. It sometimes enters into the joint itself. These cases are always to be cured by rest and counter-irritants."

Hydrothorax.—Paracentesis.—Cure.

A middle-aged man, of dark complexion and pale countenance, was admitted into the hospital some time ago, under the care of Dr. Roe, complaining of considerable difficulty of breathing, cough, and all the characteristic symptoms which generally indicate the presence of water in the cavity of the thorax. The patient's appearance was exceedingly emaciated and haggard, and he complained of a sense of anxiety in the lower part of the sternum. It appeared by the patient's statement that he had been for a long time labouring under these symptoms, which became very much aggravated by exposure to cold in returning home from the theatre a short time previous to his admission. He also complained of a constant cough, and said he often awoke suddenly from sleep in apprehension of immediate suffocation. He could lie only on the side which was affected. On percussion his chest gave a dull heavy sound, his pulse was irregular. When he moved in bed he could very distinctly feel the undulation of water in the chest.

On the 7th of August, there being no doubt entertained of the existence of fluid in the thorax (all the symptoms being particularly well marked) it was found advisable to perform the operation of paracentesis. The operation was performed in the following manner. An incision about an inch and three quarters in length, was made through the integuments between the sixth and seventh ribs. The intercostal muscles were then divided near the upper edge of the lower rib. (This exact situation should be cautiously attended

to, as otherwise there is considerable risk of wounding the intercostal artery which runs along the under edge of the upper rib.) A trocar was introduced, and about six pints of straw-coloured fluid were then discharged through a canula. The canula was then speedily withdrawn, and the wound closed up. From the time of the operation the patient gradually appeared to recover, and the unfavourable symptoms began to disappear. He was soon after put on a minim and a half of hydrocyanic acid three times a day. Nothing very important took place afterwards, and he was discharged from the hospital on the 16th Nov. perfectly cured.

Dr. Roe, in his clinical lecture on this case, observed, that the sound which was heard on percussion in the commencement of the disease, might be a symptom arising either from a solidified lung, pulmonary abscess, or the collection of fluid in the chest.

The presence of fluid, Dr. R. remarked, may be known by one certain symptom, or when on percussion we find a difference of sound produced by change of posture, that is, when the patient standing erect the breast being struck gives forth a sound different from that which it does when he is in a recumbent of any other position. Having been satisfied of the presence of water in the thorax, the next important point to be considered is how we are to get rid of it. To effect this either of two modes of treatment may be pursued; having recourse to bleeding, leeching, and blistering, or resorting at once to the operation. Dr. Roe is of opinion, that in cases where there is no obstruction of the circulation of the heart, the operation is not advisable, and that the antiphlogistic plan should not be carried too far. Dr. Roe particularly impressed on the minds of the students the impropriety of a mode of treatment pursued in some cases, viz. that of allowing the canula to remain in for some time after the operation. Dr. R. read a case from the Medical Quarterly Review, in which this injudicious treatment was followed, and the patient very soon sank.

Dr. R. had a case of a young lad at Brompton, in which the chest was punctured, and the case turned out most favourably.

Thus, observed Dr. Roe, we have two reasons for not allowing the canula to remain in; viz. the great probability of doing mischief by pursuing this injudicious treatment, and the almost certain y of the patient's recovery if this be avoided, and the operation judiciously performed. When air gets into the abdomen or testicles, inflammation succeeds, but no such consequence necessarily ensues on puncturing the thorax. The greatest caution should however be observed, and the wound speedily closed up.

Dr. Roe showed a flat trochar invented by Dr. Davis, which Dr. Roe strongly recommends in cases when the operation of puncturing the thorax is required.

MIDDLESEX HOSPITAL.

Samuel Dovey, ætat. fifty-seven, admitted under the care of Dr. Watson, February 26th.

Paralysis of the parts supplied by the portio dura of the left side, with hemiplegia of the left half of the body; he draws the leg after him in walking, and is unable to use the arm; deaf in the right ear; complains of constant pain in the head, especially over the right eye. These symptoms have existed for ten days; they came on gradually.

C. C. nuchæ ad 3viij,

Calomel gr. ij,

Opii gr. ʒ, nocte maneque.

March 5th. Since the last report he has become heavy and drowsy; cannot see distinctly.

V. S. ad 3xvj.

6th. Better after the bleeding, but there is increase of coma to-day; gums tender.

Rep. cuc. cruent.

8th. Not much better; emp. lyttæ nuchæ. Upon examining the heart by the stethoscope a rough bruit is heard, principally over the base.

16th. Another attack of stupor; stertorous breathing; face flushed, and a regular state of apoplexy. The temporal artery was opened, and relief obtained after taking 3xvj.

17th. Much more sensible; blood buffy; paralysis the same.

28th. More drowsy, and unable to be roused; evacuations involuntary. From this time he became weaker and weaker, and died April 11.

Pathological appearances, twelve hours after death.

Chest.—Some sero-sanguineous fluid in the pericardium; heart large and loaded with fat; right side healthy; except a little deposit in the tricuspid valve; left ventricle large and thicker than natural; mitral valve thickened; semilunar valves of the aorta thickened also, with depositions in the aorta.

Head.—Substance of the brain firm; the left lateral ventricle was enormously distended with clear serum, the walls of the corresponding ventricle were forced nearly into apposition by the pressure of a tumour, which occupied a large portion of the hemisphere.

The anterior portion of this tumour, about three inches in length and two in breadth, was hard and homogenous; the middle portion was yellow, and of a spongy character, while the posterior part was red and soft. At the under part of the tumour, an apoplectic clot, the size of the top of the little finger, was found. The right portio dura and mollis, where they should be separate, were found adherent; the portio dura was larger and harder than natural; the portio mollis was softened, and almost invisible at the first glance.

This case differs in some respects from the two former, but possessing so many points of interest I am induced to send it.

MISCELLANIES.

CÆSAREAN SECTION.—Doctor Shanagan, of the Townsend-street lying-in hospital, performed the operation on a woman who was killed from throwing herself out of window in the fourth month of pregnancy. The child lived for one hour and a half.—*Dub. Journ.*

EXAMINATIONS AT THE COLLEGE OF SURGEONS.—Last week the first half-yearly examination of the surgical pupils, pursuant to a regulation recently adopted, was held in the Board-room of the College of Surgeons. The students, to the number of sixty-two, were arranged into four classes, each pupil being selected for the senior or junior classes, according to his standing at the profession. The following gentlemen, members of the courts of censors and appeal, were appointed examiners:—Messrs. Colles, Jacob, Harrison, Porter, Taggart, White, M'Dowell, Hart, Benson, and Corbet. The president and vice-president, Messrs. Kerin and Kirby, were in attendance to preserve order in the court. We cannot but congratulate the learned body upon the success of their first essay at establishing a system of education which must tend so materially to facilitate the acquirement of professional knowledge in Ireland.

The Chief Secretary of State for Ireland has been pleased to appoint Dr. M'Ennally, Surgeon, R.N., 22, Lower Gardiner-street, to be Inspector of Anatomy in Dublin.

ILLNESS OF DR. PARIS.

WE are extremely sorry to inform our readers, that so able a supporter of the medical literature of this country, as Dr. Paris, is seriously ill. We have few such writers among the Fellows of the College of Physicians, and sincerely do we wish this justly celebrated physician a speedy recovery.

BOOKS.

A Series of Chemical Tables, arranged for

the Use of the Chemical Student. By R. WARRINGTON. London, 1833. John Taylor. Facts establishing the Deleterious Properties of Rice, used as an Article of Food. By ROBERT TYTLER, M.D. London, 1833. Renshaw and Rush.

Observations on the Injurious Tendency of Extreme Depletion in Inflammatory Disorders, with Remarks on the Remedial Agency of the Vapour Bath in Acute and Chronic Diseases. Illustrated by Cases. By EDWARD DANIEL, Surg. Lon. 1833. Steill, Pater-noster Row.

Clinical Observations on the Constitutional Origin of the various Forms of Porrigio; with Directions for the more scientific and successful Management of this usually obstinate Class of Diseases, by a Statement consisting of an appropriate Modification of those Principles first particularly promulgated by Mr. Abernethy. By GEORGE MACILWAIN, Surgeon to the Finsbury Dispensary, &c. London, 1833. Longman, Rees, and Co.

Principles and Illustrations of Morbid Anatomy, adapted to the Elements of M. Andral, and to the Cyclopædia of Practical Medicine, &c. &c. By J. HOPE, M.D., F.R.S., Physician to the Mary-le-bone Infirmary, &c. Part VIII. December. Whittaker, Treacher, & Co.

A Report of the Anniversary Dinner of the Pine-street School of Medicine and Surgery, Manchester.

CORRESPONDENTS.

A Student at the Westminster Hospital.—We know the charge to be unjust.

A. B. M.—It is impossible to surmise what alterations may be made; but we do not think it prudent to be articulated to a gentleman who is not a member of the Hall, though a member of the Dublin College of Surgeons and Hall. It is more probable that apprenticeships will be done away with, and a longer period of study required.

Dr. Thomson's Reply to Dr. Wallace at our earliest convenience.

Mr. Benham's Letter relative to the Portrait of the late Dr. Brookes in our next.

An Old Practitioner.—Midwifery will be protected, we believe, by the College of Surgeons.

A Stethoscopist's infirmation is under consideration.

Mr. Atkinson.—Press of matter is our excuse.

Dr. Stokes's lectures will be published in a few days.

Errata.—In Dr. Negri's Paper, page 554, col. 2, line 35, for "liver" read "loins." Page 556, col. 2, line 15, for "greatly" read "partly." Page 557, col. 2, line 47, for "Mr. Nettleford" read "Mr. Nettlefold." Page 559, col. 2, line 17, make same correction. Page 575, col. 2, line 5, for "hæmtemesis" read "menorrhagia."

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,**Session 1832—1833.*

LECTURE LXVII., DELIVERED MARCH 13, 1833.

GENTLEMEN,—Before I begin the consideration of certain *specific diseases*, which are usually treated of in a course of surgical lectures, I beg your attention for a short while to *injuries and diseases of tendons*, and *parts about them*. Some notice of these cases will very appropriately follow the account that has now been given of the diseases of joints. *Wounds extending through tendons*, if proper care be not taken, that is, if measures be not adopted to bring the separated portions of the tendon together, will be followed by the loss of the use of the muscles to which such tendons belong. The old surgeons, in order to secure the re-union of divided tendons, were in the habit of fastening the ends of them together with a suture; but as tendons, like all parts of inferior vascularity, will not bear much irritation and inflammation without being likely to slough, the old practice has been renounced.

We know very little, indeed, about the pathological changes in tendons; but, it would appear from some interesting observations made by Mr. Key, and lately communicated in a paper to the Medical and Chirurgical Society of London, that the reticular tissue, interposed between the tendinous fibres, is the medium by which the increased vascularity is produced in tendons which inflame, and are about to ulcerate. Or rather, I should say, a new vascular substance is developed in that tissue, which becomes the organ by which the phenomena of ulceration are supposed to be chiefly effected.

The right principles to be attended to in the treatment of divided tendons are well illustrated in the case of a *ruptured tendo-Achillis*,

an accident which takes place every now-and-then, in dancing, leaping, and other exercises, in which the muscles of the calf are put into violent action. It occurs chiefly in the male sex—seldom in females; and even when it happens in men, they are generally athletic and muscular subjects. At the moment of the tendon giving way, the patient feels a sensation as if he had been struck on the heel with the lash of a whip, and a noise is sometimes heard both by himself and the bystanders, as if a nut had been crushed under the heel of his shoe, or like the smack of a whip. If the part be now examined, a depression will be found in the situation where the tendon has given way, and the power of extending the foot will be considerably diminished, but not entirely lost, as some writers erroneously describe; for the long flexors of the toes, the peronei, and the tibialis posticus, yet enable the patient to extend his foot in a weak and imperfect degree. In the treatment, the first and most essential principle is to relax the mass of muscles forming the calf of the leg, and which are attached to the tendon. Of course, then, you would relax the gastrocnemius and soleus, by bending the leg upon the thigh and extending the foot: this is the proper position; but it cannot be maintained without the aid of bandages or some kind of machinery. Now, it has happened, that some men of great eminence in our profession, have met with the accident themselves, and, consequently, have been led to take a great deal of interest in the invention of the most convenient apparatus for retaining the limb in the best position. The apparatus invented by the celebrated Monro, primus, of Edinburgh, whose own tendo-Achillis was inadvertently ruptured, consists of a slipper, to the heel of which is affixed a strap, which is buckled to another strap put round the limb a little below the knee, and the heel is kept drawn up towards the ham. This contrivance, which has the recommendation of great simplicity, completely answers, as far as the foot is concerned; but you will not always have it at hand; it is a thousand to one against your being provided with, or able to procure, such an apparatus when you are called in to a case of ruptured tendo-

Achillis; therefore you ought to be prepared to do what may be requisite, without any ready-made mechanical contrivance. Under such circumstances, after bending the knee and extending the foot, apply a longitudinal compress on each side the tendon, and then surround the ankle and tendon with a roller, applied in the form of the figure 8. Next put a few turns of another roller below the knee, and let this bandage and that on the heel be connected together with a band placed along the back of the leg, by means of which band the foot is kept duly extended. In this manner you will experience no difficulty in keeping up the heel, and you need not use any particular contrivance for keeping the leg bent. If the patient be in bed, as he ought always to be at first, you direct him to keep the leg in the state of flexion; and when he gets up, you desire him to provide himself with a high-heeled shoe. The tendo-Achillis generally unites pretty firmly in three or four weeks. It is not a highly organised part, as you are aware, and therefore the rupture of it requires some considerable time for its reparation—a longer time than the union of some fractures; so that, even at the end of three weeks, a violent action of the muscles of the calf will create a risk of a recurrence of the accident. There are instances on record (and I think Mr. Hunter's own case was one), in which the cure was effected without confinement at all, merely by keeping the foot extended, and letting the patient wear a high-heeled shoe. It seems that the process, by which tendons are re-united, requires nearly as great a length of time as that by which broken bones are repaired.

With respect to *ganglions*, gentlemen, they are tumours connected with tendinous structures: they are very much like some kinds of encysted swellings—more like them than any thing else: they are filled with a fluid resembling white of egg, but their cysts are fibrous, and lined by a smooth membrane. On pressure, a ganglion feels remarkably hard; there is no elasticity about it; neither is it in general very moveable, as it is fixed at its base; but the skin over it will move about in the early stage of the case, before any inflammation has come on. The tumour is generally fixed either to a tendon or to the fibrous sheath, or theca of a tendon; but sometimes what are called ganglia are actually collections of a glairy fluid within the fibrous sheaths themselves. Generally they are round, or globular, but sometimes oblong, which is chiefly exemplified when the collection of fluid is within the sheath. Gentlemen, you will see some of these swellings about the wrist so oblong, that a part of them may be felt on the palmar side of the annular ligament, and the rest of it higher up the limb on the wrist. Such ganglions form within the loose synovial membranes of the tendons at the wrist. Ganglions are not frequently attended with pain; they form slowly; and, in most cases, the only

inconvenience, experienced from them, is a slight weakness of the muscles or joint whose action is interfered with. The patient may have a slight weakness of the fingers, or of the wrist; but, although most ganglions form on the hand, or wrist, others occasionally present themselves on the instep. I have seen several examples of ganglions on the foot. Certain subjects appear to be very liable to them; especially after bruises or sprains; but, in common instances, no such causes can be assigned for their formation. I have said, that there is a great tendency to the disease in particular individuals; at this present times, I am attending a girl, who has three of them, two of which have been formed since I commenced the treatment of the first. It is a disputed point, whether any ganglia are truly parts of new formation, that is, whether they are actually new productions or growths. I believe many of them are only collections of fluid in the fibrous sheaths of tendons, which are natural and original parts; but whether others, of a more globular, prominent, circumscribed figure, are of the same character, merely enlargements of original parts, is undetermined. Although ganglia produce little pain or inconvenience, patients are generally very desirous to get rid of them, and few persons behold with indifference any disfigurement, infirmity, or imperfection, about their hands or feet. Ganglions are sometimes rather difficult of cure; they may occasionally be dispersed by blistering, or rubbing them with liniments containing ammonia, iodine, camphor, or the tincture of cantharides. Many of them will also yield to firm pressure made on them with a piece of lead and a roller. But, after being lessened, they often return, and, on this account, instead of the plans which I have specified, it has been proposed to rupture them; that is to employ such pressure as shall burst them, and squeeze the fluid into the surrounding cellular membrane. When you can succeed in effecting this, either by striking the tumour with some obtuse body, such as the back of a book, or by compressing it against a bone with your thumbs, if it admits of it, you will generally succeed in curing the disease; for, after it is ruptured, if the pressure on it with lead or pasteboard be continued, you will almost always cause the obliteration of the cavity, in which the fluid was collected. Sometimes the cyst may be burst by pressing on it firmly with the thumbs, or by striking it with the back of a book, but occasionally you cannot succeed in rupturing it at all, so strong is the texture of the fibrous cyst. Under these circumstances it has been proposed to puncture the cyst with a couching needle, introduced obliquely through the skin and the cyst, so as to let out the glairy fluid which it contains, after which you are to keep up steady firm pressure on the part. Other surgeons venture further than this, and, after the cyst has been opened, they throw into it a stimulating injection with the view of exciting the ad-

hesive inflammation within it. Others again, venture to pass a seton through it. But examples are not wanting in the records of surgery to prove, that you should not deal too boldly with some descriptions of ganglions; for extensive inflammation and phlegmonous erysipelas have been the result of too rash a method of treatment, and, in other instances, ganglions, subjected to too much irritation, are alleged to have been converted into unpleasant ulcers, from which fatal fungous diseases arose. Possibly, these might have been, however, from the first mistaken cases of medullary sarcoma. In the writings of Mr. Abernethy, you will find allusion to instances, in which tumours, supposed to have been ganglions, were converted by the irritation of setons into diseases fully as bad as fungus hæmatodes. You will also find in the annals of surgery the histories of many ganglions, which were removed with the knife; but generally, a milder plan of treatment will answer, I think, you would not usually be warranted in undertaking the excision of a ganglion; this practice would only be right when the swelling resists other means, is occasioning much greater annoyance than is commonly experienced, and has a shape and conformation that adapt it to such treatment.

Gentlemen, I may next remind you, that the *bursa mucosa* are parts very liable to a disease. You know that these are membranous sacs, placed under tendons, and that their use is to secrete a slippery fluid, which renders the surfaces, on which those tendons play, smooth and well qualified to facilitate the perfect action and effect of the muscles. Sometimes, in consequence of sprains, bruises, pressure, or accidental inflammation, the cavity of the bursa becomes distended with a greater quantity of secretion than usual; it is therefore enlarged; and, in this state, a considerable degree of pain is experienced in the part; though, in many instances, the inflammation is of a more chronic character. You will often see this disease in the *bursa mucosa* which is situated between the patella and the skin; but sometime it takes place in the flexor tendons of the fingers, in that which is placed over the olecranon, or in that of the ball of the great toe. A curious case is related by Mr. Brodie, in which the *bursa mucosa*, situated between the latissimus dorsi and the lower angle of the scapula, was enlarged to the size of a man's head, in consequence of the disease now under consideration. The sacs of *bursæ mucosæ*, when inflamed, become considerably thickened. The fluid within them is sometimes clear, but in other instances turbid, or even purulent; and occasionally it contains numerous granular bodies, which are compared to melon-seeds, both in respect to size and shape. Substances of this kind, however, are met with only when the disease has been of long standing. You will find these swellings very common in the patella, particularly in housemaids, who are employed a good deal in scouring rooms,

in which occupation the pressure of the bursa against the floor has the effect of bringing on inflammation; hence, the disease is sometimes called the *housemaid's knee*.

Treatment.—In the first stage of the disease, while acute inflammation prevails and there is great tenderness, antiphlogistic measures should be employed, especially leeches, or even bleeding, cold applications, quietude of the limb, and brisk aperient medicines. These are the first plans for adoption. Afterwards, when the disease becomes more chronic, you may try discutient lotions, particularly those which contain the muriate of ammonia, vinegar, and a proportion of alcohol; and in a still later stage, you will find blisters, or liniments containing iodine, or the camphorated mercurial ointment, will have a very beneficial effect in dispersing the remains of the swelling. Sometimes you will find that you cannot get rid of the disease by the above plans, and this is especially the case when the tumour contains those small granular bodies, like melon seeds, to which I have adverted. There is always considerable difficulty in getting rid of them when they are of long standing, and the parietes of the bursa are much thickened; under these circumstances, it is frequently necessary to open the bursa, for the purpose of discharging these granular substances, and afterwards to excite such an inflammation in the cavity of the bursa, as shall lead to its suppuration, granulation, and obliteration. If these processes can be thus brought on, without exciting too much inflammation in the surrounding textures, then the disease will soon have a favourable conclusion. But you will sometimes find, that though you open the bursa and discharge its contents, the necessary degree of inflammation does not ensue; the bursa continuing to discharge a glairy fluid, and the integuments to be, from time to time, attacked with troublesome and painful degrees of inflammation, sometimes of the erysipelatous kind. Some time ago I had a case, in which I opened the bursa over the patella: but the disease continued to annoy the patient for a considerable time after the operation, so that I found it necessary to inject a solution of the nitrate of silver into the sac, in order to excite the requisite inflammation for its obliteration; this measure succeeded, and the patient soon got well. Some surgeons recommend the introduction of a tent for this purpose. I should mention, that you ought not to open these *bursæ*, unless it be absolutely necessary, for the operation is not unattended with danger; and you will occasionally hear of cases, in which the patients lose their lives in consequence of the operation, the limb being attacked with phlegmonous erysipelas in a violent form. There are examples, in which it is even necessary to cut away the bursa, it being converted into such a complicated and indurated mass of disease, that no common plans will cure it, and then it may be cut away, like any other tumour.

There is, gentlemen, a particular kind of tumour, familiarly called a *bunion*, a common and very painful swelling, situated on the ball of the great toe. A bunion appears to be nothing more than an inflammation of the bursa placed at the junction of the first phalanx of the great toe with the metatarsal bone. It is a very annoying complaint, and one for which you will frequently be consulted. The surrounding parts are always much indurated, and I think, that, in some cases of bunion, the bones of the joint are involved; at all events, the disease is frequently conjoined with a distortion of the bones of the toe, which seem partially luxated. In consequence of the projection of the tumour, it is greatly exposed to irritation from the pressure of the patient's shoe, and from this cause it becomes the seat of repeated attacks of inflammation; indeed, few complaints are more distressing than an inflamed bunion. The principles of treatment are simple; consisting in the removal of pressure from the part; in keeping the limb perfectly quiet; and, when inflammation is present, in employing leeches, emollient poultices, fomentations, and brisk cathartic medicines. It is found that warm applications generally suit this case better than cold ones; but if the former fail to afford ease, try the latter. Bunions are cases in which a surgeon is frequently called upon to give his advice; I know some opulent persons who are often annoyed by them; and it is right you should understand what the disease is, and what are the right principles to be observed in its treatment.

Gentlemen, I come now to one of the most interesting divisions of these lectures, namely, that which relates to certain *specific diseases*, e. g. the *venereal disease*, *cancer*, *fungus hæmatodes*, *scrofula*, and *melanosis*. Strictly speaking, there are many other diseases which would come under the denomination of *specific*; but those, which I have enumerated, usually make one section of a course of lectures on surgery. I begin, then, with that specific disease, about the nature of which you feel probably the greatest curiosity, namely, *syphilis*, or *venereal disease*. This is a subject, gentlemen, to which both your duty and your interest mutually invite your earnest attention. The alleged Protean character of the venereal disease, a circumstance apparently inconsistent with the expression *specific*; its severe consequences, when unskillfully treated; its great frequency; and its being a main source of emolument to our profession; must render it a matter on which you must be desirous of acquiring information. It was, indeed, in consequence of the encouragement which Syphilis affords to surgery, that I expressed a suspicion in a former lecture, that she might have a superior claim to that of Podalirius, to rank as one of the supporters of the College arms. (*a laugh.*) Syphilis is generally supposed to arise from a specific morbid animal poison, which, when applied to

the human body, frequently produces changes in the part to which it is immediately applied, and also, sometimes effects in other parts, in consequence of its absorption and introduction into the system. The disease cannot be propagated from individual to individual through the medium of the atmosphere, it is therefore *contagious*, but not *infectious*; neither can it be communicated through the medium of the breath, nor probably the various natural secretions; nor by one person merely touching a sound part of the skin of another individual affected with the disorder. With the exception of what may happen between the mother and the foetus in utero, there is only one manner positively known, in which the disease can be communicated, and that is, through the medium of its peculiar poison, blended with a purulent secretion; there is also another condition seemingly essential, or believed to be so, according to the Hunterian doctrines, namely, the purulent secretion, capable of transmitting the disorder, must be the product of a *primary ulceration* or *abscess*; and not the product of a *sore* following, and proceeding from, the absorption of the poison into the system as a secondary effect of the disease. A primary sore means, as I need hardly say, one that is caused in a part by the immediate application of the contagion to such part. This doctrine, which has Mr. Hunter as its advocate, deserves, I think, to be well remembered. All the effects and symptoms of the venereal disease are divided into *primary* and *secondary*; the former being those which arise either from the direct application of the virus or poison to the part, where the first ulceration shows itself, or from the irritative and specific effects of the poison on the absorbent vessels and glands, as it is passing through them on its way into the circulation. Hence, there are two kinds of primary symptoms; first, the ulcer, arising from the application of the poison to the skin, or a mucous membrane; and secondly, the inflammation, swelling, or abscess produced in the absorbent vessels or glands by the venereal poison, while it is pervading them. The purulent secretion from these two kinds of primary affections is universally acknowledged to be capable of transmitting the disease; but the matter from secondary sores is not usually considered to have the same power. The *primary ulcer*, or *chancre*, as it is commonly called, must necessarily be situated, in almost every instance, on the parts of generation, and it may, or may not, be followed by an inflammation or abscess in the absorbent glands of the groin, constituting that kind of complaint to which the name of *bubo* is applied. The *primary ulcer* then is termed a *chancre*, and the swelling of the absorbent inguinal glands, which is also an effect of the operation of the poison previously to its reaching the circulation, a *bubo*. The application of venereal matter to the skin does not invariably produce a chancre, or any

other complaint; experience proves that many individuals who cohabit with women, known to have chancres, and to have given the disease to others, are fortunate enough to escape unhurt; and there are persons seemingly insusceptible of the disease, though they are continually exposing themselves, without any regard to the cleanliness or soundness of the objects of their amours. A certain organ is put into the fire, without being injured, just like the horny hand and fingers of a blacksmith can touch iron nearly red hot without harm (*a laugh*). When an individual is careful to wash himself after coition with a suspected person, he will be less likely to suffer than he otherwise would be. Neither does the poison, which has given rise to a chancre, always produce a bubo; and this, even when it has found its way into the system, so as to produce secondary symptoms. You will meet with many instances of chancre, in which there is no swelling in the groin, yet afterwards there will be sore-throat and venereal eruptions on the skin.

In the next place, gentlemen, with respect to the *secondary symptoms*, they may be defined to be *all those effects of the disease, which take place subsequently to, and in consequence of, the absorption of the poison into the system*; comprising sore-throat, cutaneous affections, both eruptions and ulcers, pains in the bones and joints, nodes, caries, and necrosis. Such is the great diversity of secondary affections. The secondary symptoms, however, do not follow the primary ones with any kind of regularity; and, in some individuals, they may never show themselves at all, while, in others, they will come on with an unusual degree of severity, though, as far as we can judge from the appearance of the primary sores, there is no marked difference between those which heal up without secondary symptoms, and the others which are followed by secondary symptoms. Neither can we always explain this diversity by referring it to the different modes of treatment adopted; you will find, that out of a given number of patients, all treated in the same manner, some will suffer severely from secondary symptoms, and others will entirely escape them. It may be asked, is it possible to account for these different consequences by supposing some peculiarity of constitution, or some particular circumstance to be exerting an unfavourable influence while the patient is under treatment? No doubt, the temperament and mode of living modify the venereal disease, as well as all others; but, as it would be premature to enter now upon the difficult points connected with this part of our inquiry, I will not detain you upon them at present.

Syphilis, then, is propagated by the application of the matter secreted from a primary venereal sore called a *chancre*, or from that of the abscess, called a bubo; and the matter of a secondary sore is not generally deemed to

be capable of communicating the disease; such at least was the conclusion, at which Mr. John Hunter arrived. The contrary fact has often been suspected, but never satisfactorily proved; and indeed it is a difficult thing to prove, because, the experiments required to settle it are revolting to humanity; but, as far as we can depend on the observations of the most experienced men, and especially on the researches of Mr. Hunter, who paid so much attention to this subject, we may set it down as tolerably certain, that the matter of secondary sores will not communicate the disease.

At the present day, writers extend the meaning of the expression *venereal disease* further than was formerly understood by it; for they make it comprehend not only *syphilis*, or the *true venereal disease*, but also *gonorrhœa*, sores of different descriptions on the genitals, and numerous effects or accompaniments of the latter complaints. Such writers do not speak of the *venereal disease* in the singular, but in the plural number, and offer a description, not of one disorder, but of several, under the appellation of *venereal diseases*. Others, aware of the difficulties in the way of a satisfactory explanation of all the puzzling and incongruous circumstances observed in venereal patients, are induced to believe in the existence of several kinds of venereal poison, each of them capable of producing distinct and peculiar effects on the part and the constitution. Thus Mr. Carmichael espouses the doctrine of there being more kinds of syphilis than one, and has written a treatise on *venereal diseases*, highly valuable as a practical work, whatever may become of the theory to which I have alluded.

The antiquity, or the comparatively modern, origin of syphilis, is a disquisition of great curiosity to all, who take up the study of disease with a spirit devoted to the cause of truth, and to the many philosophical topics of research which the pursuit of our profession affords; it is an inquiry, in which the most intelligent men, however, have been led to different inferences. The questions are, whether the disease originated towards the close of the fifteenth century, and was at that period brought to Europe by the followers of Columbus? Or whether it arose spontaneously about the same time in the French army employed in besieging Naples? Or whether, it has always existed from time immemorial? If it were of modern origin, you would excuse me, I am sure, from giving any opinion on the question, which nation had the honour of giving birth to it? (*a laugh*).—this is a delicate point that may well be left to the French and Neapolitans to settle between themselves. The *French* call it the *Neapolitan disease*, and the *Neapolitans* retaliate by calling it the *French disease*. For my own part, I never adopted the common opinion, that syphilis was imported from St. Domingo into Europe

by the followers of Columbus; it seems to me, there is no proof that such was the case; and, when various particulars are considered, we shall find that some of them militate very strongly against that opinion. Supposing the disease to have existed in St. Domingo sooner than elsewhere, and to have been brought to Europe by the followers of Columbus, we should expect, that it would have broken out in Spain itself, where the sailors and soldiers of his expedition first landed after their return, and not in Italy. Then we are to consider, whether the disorder, that was observed about that period in Italy, truly resembled in its general character and effects what is now called syphilis;—I think there must be infinite difficulty in coming to the conclusion, that the disease, which broke out in the French army in Italy at the close of the fifteenth century, was the venereal disease, when you are informed that it spread among the soldiers so rapidly, and with such malignity, as to destroy in a short time a considerable part of that army. This is by no means the nature, or course, of the modern venereal disease; and, if it were, I suppose, it would thin our population more quickly than the present epidemic cholera. The venereal disease is indeed sometimes attended with violent effects on the health, with terrible ulcerations, with afflicting pains and mischief in the bones, and with other alarming and dangerous consequences; but it is not the nature of the disease to assume these aggravated forms in a sudden manner, or to destroy the patient in the rapid and unmerciful way displayed in the ravages of the disease, which broke out in the French army at the siege of Naples. So far is this from being the case, that it is one of the laws of the venereal disease for a certain interval, or, perhaps, I should rather say an uncertain interval, should always transpire between the primary and secondary symptoms. Be it also remembered, that the disease which proved so fatal to the French army, could be transmitted from one person to another by breathing the infected air, by touching a sound part of the patient's skin, or even by mere residence in the same chamber with him, without touching him at all. No complaint, having the characters here mentioned, would now be regarded as syphilis. In all probability, the disease in the French army was an epidemic febrile disorder, attended with ulcerations, buboes, abscesses, &c.; and at all events, it was a disease not resembling the modern lues Venerea, which is slower and milder in its progress, not contagious, except by the application of matter containing the poison to the skin, or a mucous membrane; never sweeping off thousands at once in the rapid manner described by those who have detailed the particulars of the disease, which nearly annihilated the French army in Italy; and never extending itself through kingdoms and armies with the quick fatality, malignancy,

and swiftness, noticed in the Neapolitan epidemic of the year 1495.

Gentlemen, I will go on with this subject to-morrow evening.

CLINICAL LECTURES

DELIVERED

At the Meath Hospital, or County of Dublin Infirmary, Session 1833-34.

BY PHILIP CRAMPTON, M.D., F.R.S.,
Senior Surgeon to the Meath Hospital, Surgeon-General to the Forces in Ireland, &c.

LECTURE III.

Treatment of Fractures.

GENTLEMEN,—At our last meeting I gave you an outline of the pathology of fractures; you will, therefore, be better prepared to enter upon the treatment of those injuries which shall be the subject of this day's lecture.

The principles which regulate the treatment of fractures, or wounds of the bones, are precisely similar to those which regulate the treatment of wounds of the soft parts; they are accordingly few, simple, and easily remembered. You know, that the first principle, in the treatment of simple wounds, is to bring the divided surfaces into the most perfect apposition, at the earliest possible period, and by the gentlest possible means. As soon, therefore, as the bleeding has ceased, we bring the surfaces in contact, and to effect this purpose, we depend much more on relaxing the wounded muscles by position than on drawing them together by sutures, or pressing them together by bandages. It is the same in fractures. If the bones of the leg or thigh be broken obliquely, and the limb be shortened by one fragment overlapping the other, we do not attempt to bring the broken surfaces in contact by pulling at the limb until, by main force, we overcome the contraction of the muscles, but by bending the leg upon the thigh, or the thigh upon the pelvis, as the case may be, we relax the muscles, which act most powerfully, and in this way elude rather than overcome their force.

In the treatment of wounds the second indication is to prevent or allay inflammation, for inflammation is always opposed to union; it is the same in fractures. In wounds we endeavour, by adhesive plaster and bandages, to keep the surfaces in contact until union is perfected; in fractures we employ, with the same view, our bandages and splints. In lacerated wounds of the soft parts, attended with loss of substance, and where union by the first intention cannot be expected, we wait patiently for the subsiding of the inflammation, and the formation of granulations, which are to establish a new bond of union between the divided surfaces. When these are formed, we assist nature in her efforts by gently drawing the parts together, and by supporting the consti-

tution, if the suppuration, attendant on this union by granulations, should be profuse. The same principle is strictly applicable to the treatment of compound fractures.

All this is indeed very simple; but when we come to the details, when we come to deal with particular fractures, and that the whole management and responsibility devolve upon ourselves, we find such complications in the local injury, or in the constitutional disturbance, or in both, that unless we have an ample fund of experience to draw upon, we shall find that our general principles, however just, will afford us but little assistance. The use of clinical instruction is to assist you in the laying up of this fund, and it is attended with this peculiar advantage, that each particular case, while it furnishes us with a practical precept, assists in establishing a principle of more general application.

There are a few details with respect to the management of fractures of the extremities *in general*, which even the experience of an hospital cannot supply;—to these I should wish to direct your attention before I proceed to describe the management of particular fractures, and to illustrate the treatment by a reference to the cases now in the house. In all matters, whether of science or art, it is a point to “begin by the beginning.” A surgical student, who had seen, or even assisted, at the doing up of a fractured leg or thigh one hundred times, and who, when his patient was laid comfortably in an hospital bed, put on every part of the most complicated apparatus for fracture with the most perfect propriety and neatness, might feel himself at a loss how to proceed when he found his patient, with a broken leg or thigh, lying at the bottom of a ditch, or in the middle of a field, at the distance of it might be two or three miles from any assistance. This is a part (a most important part too) of the treatment of fractures, which is but slightly touched upon by systematic writers, and to this I would now intreat your individual attention. The object is to remove the patient home with the least possible disturbance to the fractured limb. It must be plain to you, that when the sharp chisel-shaped extremity of a fractured tibia has nearly cut its way through the integuments, that a very slight degree of motion communicated to the bone in the same direction, will drive it quite through, and thus convert a simple into a compound fracture. Before you make a single move, therefore, you must digest your plan of operations, and as presence of mind on such occasions is as much the result of knowledge as of natural constitution of mind, you must give yourself time to bring your resources into play, and to make up by reflection for what you want in experience. Your first object, then, should be to restrain the motions of the limb, particularly at the fractured part. If you find, from the deformity of the limb, or from its mobility when you touch it, that the patient's apprehension is well founded, (and

he is seldom mistaken,) and that the bone is broken, you do not fall to work in pulling off his boot or breeches, in order to examine the wound, but you bind your handkerchief or neckcloth firmly round the limb, to which the boot (in case of fracture of the leg) forms a tolerably good splint. You then desire the patient, if he is lying at the bottom of a ditch, or pit, to clasp his hands round your neck, and passing your own arms under his axilla, you draw him up, allowing the limbs to trail along the ground, warning him, at the same time, not to give any assistance, but to lie as if he was dead. In the mean time you must command yourself so as to betray no alarm, for nothing will so much increase the terror of your patient, and diminish his confidence in your resources, as the appearance of trepidation, or even of hurry on your part. Cheer him, therefore, while you are assisting him; tell him that the fracture is a slight one, that you will soon make him perfectly comfortable, and that you will not leave him until you see him safely in his own bed. This may appear a trifling matter and beneath the dignity of science, but the object of our science is the relief of suffering, and he who will “administer to a mind diseased” performs one of the most delicate and difficult, but at the same time, one of the most useful offices of his profession. I lately saw a person, who had met with a most severe and dangerous fracture of the leg; the family, servants, and neighbours were standing round the bed, in a state of the most uncontrolled agitation; the patient, who was possessed of great firmness, suppressed her own feelings in consideration of those of her family, but it was plain that she was struggling against the deepest emotion, and that the pain of the fracture was as nothing in comparison with its apprehended consequences. While I was examining the limb she fixed her eyes on me with an expression of intense anxiety, but said nothing. “Come,” said I, “all's well; you will suffer a little pain for a few days, but I know you don't mind that, and in a few weeks you will be dancing.” “Thank God, thank God,” she exclaimed, (with a voice expressive of the utmost gratitude and joy;) “oh! sir, your good spirits are worth a thousand pounds.” From that moment up to this her cheerfulness has never deserted her, and I am firmly convinced, that her recovery, should she happily survive, may be very much attributed to the happy and cheerful state of her mind. I do not mean to say, that she does not derive support from those higher motives, which a religious and well regulated mind supply, but I am quite sure that cheerfulness and kindness on the part of her medical attendants (and singly those qualities are comparatively of little use) will, without interfering with those higher motives, tend as much as any part of the medical treatment to support her under her long, painful, and dangerous illness.

But we must return to our man who has

been lying all this time on the ground with only a handkerchief bound round the fractured leg. The next thing to be done, is to devise some means of carrying him home with the least possible disturbance of the fractured limb. Here is a splint which I contrived long since, and which has done good service in this way. Nothing can be more simple than its application. Having extended the leg so as to bring the fractured bones into their proper position, you place it on the heel in this hollow case and laying this pasteboard splint, which has been moulded on a sound leg along the shin, you gently compress the limb, either by drawing together three straps, or by rolling the whole leg, splints and all, from the foot to the knee inclusively.

When the leg is made up in this way, the patient may be carried in any sort of vehicle without suffering the slightest inconvenience from its motion. But it may happen that a splint of this kind will not be at hand. Well then you may make a very good substitute for it from materials that may be procured anywhere. Get a lath, or even a common straight twig, about three feet in length, place it in the centre of a junk, or long bundle of straw or hay, about as thick as your arm, fix this pretty tightly round the limb with some packthread, so as to give it a considerable degree of firmness; place three or four such junks along the limb, and then, when due extension is made, apply a roller (a hay-band or rope is as good as any) from the toes up to the knee. A limb so made up may be carried with perfect safety in any kind of vehicle, but none is so convenient as the common outside jaunting car of this country. The patient can sit at one end of the car and lay his leg along the cushion, which is of sufficient length and breadth to accommodate it perfectly. The leg can be steadied by a person sitting on the same seat to make all safe, and the interval between the leg and the back of the seat may be filled up with hay. I have in this way safely conveyed persons with broken limbs for many miles over the roughest roads. Fractures of the thigh are to be dealt with, in the first instance, after the same manner, with this difference, that the junks should be of sufficient length to extend from the hip to the foot.

There is another method of carrying a person with a fractured thigh, which is exceedingly simple and perfectly safe. Lay a firm slip of wood, of from two to four inches in breadth (and of sufficient thickness to be inflexible) from the tuberosity of the ischium to the heel of the *sound limb*. Bind it on firmly, and then bind the limbs together from the ancles to the trochanters. The patient so bound up looks like a mummy, and is just as inflexible. He may now be placed on any kind of carriage, without the least risk of injury from the displacement of the bones. He may now be conveniently carried in a chaise, by placing him on a narrow board, and passing the board across the chaise, through

one door and out at the other. I had a gentleman conveyed in this way a distance of twelve miles without injury or pain.

I shall illustrate the after treatment of simple fractures by a reference to the numerous cases of the kind at present in the hospital, I may, however, now very briefly observe, that in a case of simple fracture, where the leg is placed in this hollow back splint, with a proper shin-piece along the tibia, it is seldom necessary to confine the patient to his bed for more than eight or ten days at the utmost. One of the first persons on whom I placed this splint was the turnpike man at Finglass. He remained in bed but three days, and during the remaining thirty-five he sat at his door for several hours daily collecting the tolls.

With respect to the treatment of compound fractures *in general*, the complications which are attendant on this description of injury are so various, that there are very few general principles indeed which can be safely applied to every case. There are one or two, however, which should never be lost sight of. The first is, to endeavour in all cases to reduce, or if that cannot be done, to remove the projecting portion of the fractured bone, and to unite the wound in the soft parts, so as (if I may so speak) to convert the injury from the state of a compound to that of a simple fracture. But if you attempt to reduce the bone by force, either by extending the limb violently, or by pressing on the bone strongly, you will cause a train of the most dangerous symptoms. The wound of the soft parts which has been sufficient to allow of the protrusion of the bone is rarely sufficient to admit of its return. Inflammation of the soft parts rapidly contracts the opening, and the contraction of the wounded muscles changes its direction; the lower fragment is drawn up under the upper one; a tight band or collar of skin lies against the lower surface of the bone (in this way), so as effectually to prevent its repassing through the wound. Under these circumstances the clear course is to slit down the wound freely with a probe pointed bistoury, and if a sharp pointed portion of the tibia, stripped of periosteum, still shows a disposition to protrude, saw it off with a fine saw, protecting the soft parts beneath with a spatula, or thin piece of wood, or you can remove it very conveniently with this chain saw, working the instrument upwards in this manner. (Mr. Crampton here exhibited the chain saw, and exemplified the mode in which it should be employed.)

Another general principle to be kept in view, which, however, has reference rather to the progress than the treatment, is, that compound fractures are dangerous directly in proportion to the violence or momentum which has caused the fracture. A wound two inches in length, with a portion of the tibia protruding, the limb swollen and distorted by the retraction of the foot, if it be caused by a force acting with so little velocity that it amounts to a strong degree of pressure rather than to a

collision (as when a man slips off the curbstone in the street, or receives the weight of a horse or other heavy body obliquely on the limb), such an injury is immeasurably less dangerous than a wound not more than half an inch in diameter, with scarcely any apparent lesion of the soft parts, but which has been caused by a musket-ball passing through the bone. In the first case, the bone has probably been but just broken across at one point, and forced slowly through the soft parts, which are often so slightly injured, that when the bone is replaced they unite by the first intention, and the fracture becomes consolidated as quickly as if it were a simple one. In the other case, the bone is frequently split from one end to the other; large portions of its substance are, at all events, completely detached, and deprived of vitality by the violence of the shock; in such a case, the limb is rarely saved, and never without many months of suffering from repeated suppurations and exfoliations, which bring the patient to the very brink of the grave.

There is one point more respecting compound fractures, to which I must briefly advert, as it properly belongs to the general consideration of the subject; I allude to that peculiar derangement of the nervous system which not unfrequently appears shortly after severe injuries of the extremities, and which has been termed *traumatic*, or, by Dupuytren, *nervous delirium*. This affection has a close analogy to the delirium tremens of habitual drunkards; indeed, so far as the symptoms and indications of cure are concerned, the affections may be considered as identical, the difference being only in the exciting cause. When the delirium is connected with external injury, the process is less unfavourable than when it occurs after excessive drinking, abstracting, of course, the dangers from the injury itself—dangers which may be very much aggravated by the madness, as one of the distinguishing features of this affection is the total insensibility to bodily pain, which it produces. A person who gets this delirium as a consequence of compound fracture of the leg, or compound dislocation of the ankle joint, will, if not restrained, spring from his bed and stamp about the room on his shattered limb without evincing the slightest symptom of distress or inconvenience. The first case of the kind I ever saw occurred while I was an apprentice in the Old Meath Hospital. I heard a man singing vociferously on the stairs, and being sent to desire him to return to his ward, I found him sitting on the lobby, with his foot, which had suffered a compound dislocation but two days before, thrust through the bannisters, and he was working his limb backwards and forwards while he sang. On being reproved, he declared "that he would not stop until he had twisted off the foot, for it was of no use to him."

The cause of traumatic delirium is, like other affections of the nervous system, most

obscure. It seems, however, to have more relation to the temperament of the individual than to the nature or degree of the injury, as it appears almost as often after a slight wound, or after a surgical operation, as after a severe compound fracture of the leg. I think, however, that it is most frequently observed in connexion with injuries of the great articulations, as the knee, ankle, and elbow joints. It seldom affects women, and has not been seen in children; and I suspect the predisposition to it is formed by the intemperate use of fermented liquors. It generally attacks the patient suddenly, and you have no indication of its approach; but you may be almost sure that it is about to appear if the patient is sleepless, and disposed to toss about the bed; and if, though rational when spoken to, he mutters when alone, and draws back the curtain every now and then with an anxious expression of countenance, as if he expected to see somebody concealed behind it. The delirium runs upon various subjects, but the prevailing impression usually is, that he is pursued by the officers of justice on account of some crime which he has either committed, or of which he has been falsely accused. The crime most commonly has some relation to the profession or occupation of the individual; but whatever may be the species of delusion, it is invariably attended with a high degree of excitement. There is no degree of violence which the patient is not ready to inflict upon himself, but he is not disposed to injure others. Terror seems to be the deep and all-pervading emotion, and this affords a key to the moral treatment of this affection, which I have to recommend, in the very strongest manner, to your attention.

With respect to the constitutional symptoms which accompany this form of delirium, the most remarkable are the profuse perspirations with which the body, but particularly the face and neck, are bedewed, the tremulous and almost quivering state of the whole muscular system, the deadly paleness of the countenance, and the smallness of the pulse. Baron Dupuytren thinks the pulse is always undisturbed;—this does not accord with my observation, for I am quite sure that I have often found it exceedingly rapid as well as small.

With respect to the medical treatment, bleeding, local and general, which was formerly so much relied on, is now, I believe, universally admitted to be injurious here as in delirium tremens; our chief reliance is to be placed on opium, and the application of cold to the head. Baron Dupuytren recommends the opium to be given in the form of enema, ten or fifteen drops at a time, until sleep is procured; he is of opinion that the opium is quite ineffectual when taken by the mouth, and thinks this difference in the effect of the medicine may be accounted for physiologically, by supposing that the digestive powers of the stomach decompose the opium, and thus prevent its ordinary operation; but as there is no such

power in the rectum, he conceives that the full effect of the remedy is produced on the constitution. If this were the case, it is obvious that other medicines as well as opium should act more powerfully when administered by enemata than when taken into the stomach, a circumstance which is contrary to general observation. I have tried opium in both ways in traumatic delirium and in delirium tremens, and I cannot say that I have found the one mode of administration more efficacious than the other. I think ten drops of the Lancashire black drop every hour, until rest is procured, and an iced lotion to the head, is as effectual a mode of treatment as any that can be employed, and I prefer giving opium in this quantity to the excessive doses which you will read of in some of the medical journals. But useful as opium unquestionably is, I am quite sure that the surgeon performs but a small part of his duty in the management of this disease, if he omits the moral treatment. I stated, that one of the peculiarities of this disease was the overwhelming sense of terror with which the patient is affected; another is the unbounded confidence which he reposes in some person who he supposes has the power to protect him. Instead, therefore, of tying the unfortunate being to the bed, or putting on a strait waistcoat, if any person in whom he has confidence will stay by him and soothe him, he will in a short time become perfectly amenable. I saw, not long since, a young officer suffering from traumatic delirium; three or four soldiers could with difficulty hold him in the bed; his desire was to jump from the window, in order to make his escape before the sentence of a court martial, which he supposed had condemned him to be publicly flogged in the barrack-yard, should be carried into effect. For several hours he never ceased calling for the colonel, in order that he might implore his intercession to have the punishment exchanged for death. I brought the colonel, a most kind and sensible man, to his bedside; he took him by the hand, and assured him over and over again, that the whole thing was a mistake, and that he had come to send away the guard that was over him. The soldiers were dismissed, and in a few minutes the young man became perfectly tranquil, and remained so during the whole night. The colonel never quitted his bedside, indeed he could scarcely do so had he been so inclined, so firmly did the young man hold his grasp. Meantime the colonel continued with the most persevering kindness to assure him that there was no charge against him, and towards morning the patient fell asleep, and awoke free from all delirium. I cannot help thinking, that had this young man been held down in his bed by three or four soldiers, every additional struggle adding to his delirium, and increasing the amount of mischief done to the limb, the result of the case would have been far otherwise, not only threatening unfavourable consequences to the

local injury, but even to life itself. I could give cases without end, in which, by a judicious moral treatment, the wildest excesses of delirium have been controlled, and where a few hours spent in soothing and tranquillising the sufferer have succeeded in bringing about the restoration of reason and a refreshing sleep.

Tetanus, which is another affection of the nervous system incident to compound fractures, is too extensive a subject to be introduced at the conclusion of a clinical lecture, I must, therefore, postpone the consideration of it to a future day.

With respect to the treatment of fractures *in particular*, I believe the best method of proceeding will be to illustrate each particular form of fractures from an individual case now under treatment in the house. This will occupy a good deal of your time, but I doubt if it could be employed to a better purpose. Let us begin with the case of Craig, the woman in the accident ward, who has a simple fracture of the fibula. Simple as this case may appear to you, I consider it to be one of the most important in the house, as it depends altogether on our management of it whether the woman is restored to the perfect use of the limb, or remains a miserable cripple for the rest of her life. The principle on which you are to proceed in managing a fracture of the fibula can only be understood by a reference to the anatomy of the ankle joint, (here Dr. Crampton demonstrated the anatomy of the ankle joint, pointing out the manner in which the astragalus was supported on the inside by the malleolus internus of the tibia, and on the outside by the extremity of the fibula.) Now, it must be plain to you, that in proportion as the fracture of the fibula approaches towards its extremity, so must the support which the astragalus derives from it be weakened; and if the upper extremity of the lower fragment be pressed inwards, in this way, and made to touch the tibia, then the astragalus is deprived altogether of its external support. The foot then being drawn outwards by the abductor muscles, the weight of the body falls on the inside of the medial line, and dislocation of the foot *outwards* to a greater or lesser extent is the necessary consequence. Now in the case of Craig, the fibula is fractured at the distance of about two inches from its lower extremity. She states that in running across some broken ground, "her foot turned under her *inwards*," that is to say, its under edge was turned *outwards*. "She heard something snap at the same time, and her pain was so great that she could not again lay her foot to the ground;" and very well for her it was that she did not do so, for the weight of her body would have caused simple dislocation of the foot outwards. Well, how was the fibula fractured in this case? Just in this way.—The foot being forced violently inwards, the strong *inelastic* lateral ligaments which pass from the extremity of the fibula to the tarsus are brought to act at right angles on the bone, while the

sharp edge of the astragalus pressing outwards acts as a fulcrum upon which the fibula is snapped across. In *this case* then, the fibula was fractured by the traction of the ligaments, and not by any *external* force. But the fibula may be fractured in another way, as in the case of the brewer's man in the male accident ward, when the foot is forced *outwards*, and the weight of the body falling on the inside of the median line, the strong internal lateral ligament is put upon the stretch, acting in a direction perpendicular to the axis of the tibia; here the internal lateral ligament either separates from its attachment to one of the bones and is torn through, or, what is more common, it carries off with it a small portion of the lower end of the tibia. The lower part of the astragalus is now brought to bear against the inner surface of the fibula at its very point; and if the force be sufficient, the bone gives way at a distance not greater than two inches, or less than an inch, from its extremity.

It appears then, that although fracture of the fibula may take place without dislocation of the astragalus or ankle joint, dislocation of the ankle joint cannot take place, under these circumstances, without fracture of the fibula, and, it may be, of a small portion of the lower end of the tibia.

Now as to the treatment of this injury, I need only refer you to the case of Craig, and of the brewer's man, whose name I forget, but who was admitted yesterday. The object of the treatment in both cases is to keep, by means of a suitable apparatus, the foot in a state of the utmost adduction, and avoid all pressure above or over the fracture, the effect of which you know would be to press the lower extremity of the fibula outwards, and the fractured portion inwards. The foot when properly arranged should resemble a natural club foot; in this state it should be retained for twenty-five or thirty days. The bandage may then be taken off, and the splint removed, but the patient should not bear firmly on the foot for six weeks from the time of the accident.

The peculiarities respecting the pathology and treatment of fracture of the fibula have not been overlooked by J. L. Petit, Bromfield, Pott, Boyer, and C. Bell; but we are indebted to Baron Dupuytren for the first clear exposition of the principles on which the treatment should be conducted, and for a most beautiful, simple, and effectual means of carrying those principles into effect. I would recommend the baron's valuable and elaborate essay on the fractures of the fibula to your particular attention.

A considerable degree of stiffness and weakness of the joint is apt to remain for a long time after a fracture of this kind. Its restoration to a healthy state may be very much promoted by the warm salt water douche, by the local vapour bath, and by frictions with some animal oil.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES
OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XI.

Mercenary Lactation—Choice of a Wet Nurse.

GENTLEMEN,—I have now to describe the causes which disqualify women for the delightful duty of lactation; and these are physical and moral. I laid it down as an axiom, that all healthful women ought to suckle their infants; but few are in a state of perfect health according to the opinions of our profession. Many women are affected with constipation, or confinement of the bowels, accompanied by more or less indigestion, flatulence, spasm in the abdominal and thoracic muscles, the various degrees of hysteria, from a sense of a ball in the throat, or sense of choking, to a regular fit of the disorder, nervousness, lowness of spirits, biliousness, besides incipient disease in some important organ, as the lung, liver, &c. Persons so affected are not in good health, will be debilitated by lactation, and are unfit to nurse. These individuals may have an abundance of milk, but they supply a thin serous fluid inadequate to the proper nutrition of infants. When a woman is predisposed to phthisis, disease of the liver, or is affected with scrofula, deformity of the spine from mollities ossium, &c., from rickets, leucorrhœa, or any severe puerperal disease, she should renounce lactation. A woman who has a very small quantity of milk, as often happens to those who become mothers at a very early or advanced age, is a bad nurse. Some women have no secretion of milk, and this want, or disease, is termed agalacty. It often happens that the secretion of this fluid does not commence for two or three days after delivery; but if the breasts are properly developed, there may be an abundant supply in the course of a week afterwards. When the milk is too serous or thin, it may cause griping colic, or a frequent discharge of urine in the infant, and the mother ought not to suckle. When the woman is affected with disease in the head, chest, or abdomen, or in any part of the body, or is very thin, or is delicate, she should not nurse. This is the general opinion of our profession. The celebrated Rousseau, whose writings on the education of infants were of infinite service, held that an infant could not be injured by the blood of the mother which nourished it. This is a great error. The renowned Morton maintained another erroneous opinion, that consumption was arrested by lactation. The disease is certainly mitigated by pregnancy; in consequence of the determination of blood to

the womb for the nutrition of the fœtus; and, according to some physiologists, because nature is anxious to supply an infant in place of its mother. But so soon as delivery happens, the blood is determined to the chest, the consumption increases, and the woman speedily dies. The process of lactation is not a sufficient counter-irritant to arrest the destructive disease in the lungs, while the debility it produces accelerates the fatal termination. Moreover, we often see women who are not consumptive, who, at the end of a protracted lactation, complain of pains in the back, chest, and abdomen, accompanied by severe or violent cough, copious puriform expectoration and hectic fever, with all the appearances of phthisis. We immediately advise ab lactation, or weaning; and then all the symptoms disappear, unless in those cases in which there is a disposition, or, to speak technically, a predisposition to consumption. In such cases lactation for four or five weeks may perhaps be advisable for other reasons,—to prevent puerperal or child-bed diseases; but I cannot agree with that able and justly celebrated professor, M. Gardien, that this is beneficial, because there is, in my opinion, very little probability that a consumptive woman will, after delivery, be affected with any of the dangerous puerperal inflammations or fevers. It may be so; but I have never seen an instance, though my observations are not the most limited. Neither can I approve of another suggestion made by the same authority, that the mother may be ensured the advantage without injuring the infant, by applying a young dog to make suction, which will prevent engorgements of the chest, or the acceleration of consumption. It appears to me, that in a well marked example of phthisis, any kind of suction is highly prejudicial.

Women affected with rickets, scurvy, scrofula, cutaneous eruptions, gravel, stone, gout, syphilis, &c. are said by some to transmit these diseases to their infants, or to those they suckle. Violent hysteria disables a woman from suckling. Those who are in delicate health from whatever cause, will be greatly injured by lactation. They soon experience weakness in the back, sinking at the stomach, loss of appetite, extreme paleness of the countenance, or blanchness, which our Gallic contemporaries term *etiolation*. The bowels are generally confined, though sometimes relaxed, and there is considerable emaciation. When these symptoms appear, lactation ought to be discontinued, and if this should not be done, the infant will require artificial aliments. When there is malformation or flattening of the nipples, suction must be made by an older child, by the various breast-bottles, or by an adult.

A woman who is a nurse, ought to avoid balls, theatres, and crowded assemblies, as well as all frivolities, as her infant cannot be deprived of its natural food for several hours, and will not be properly nourished by any

other description of aliment. As a general rule, when pregnancy or menstruation occurs, the milk of delicate women is deteriorated, and other food is necessary for the infant, and ab lactation or weaning should be commenced. Some of the older authors, as Van Swieten, Lamotte, Puzos, and others, stated that they had seen very strong and vigorous infants nursed by pregnant women; but in general, the secretion of milk is diminished by conception, and its quality deteriorated. It is also true, that many of the lower animals continue to give milk for some time after impregnation. When the infant continues to thrive after the recurrence of menstruation or pregnancy, lactation may be protracted for some time. If the infant appears languid, wastes, is affected with hiccup, griping, or passes depraved alvine motions, ab lactation is necessary. Nursing is injurious to the mother and infant when the former labours under any acute or chronic disease, as fevers, inflammations, liver complaint, spitting of blood, &c. The passions of the mind alter the quality of the milk instantaneously, and render it injurious to the infant. All tumultuous passions act violently and rapidly, and the others act more slowly but with equal certainty. When an infant is suckled while the mother is in a fit of rage, it may be suddenly attacked with convulsions or diarrhœa. Sadness, inquietude, fear, shame, envy, jealousy, and chagrin, injure the breast milk.

It is scarcely necessary to observe, that the physical and moral causes which oppose lactation, or suckling, prevail more in cities and large towns than in the country. Mental anxiety during labour may prevent the secretion of milk for a few hours, but if the breasts are well developed, they will perform their function. An excellent illustration of this fact was given by my friend, Professor Graves, in the *Dublin Journal of Medical and Chemical Science*. He was requested to visit a young lady immediately after her first delivery, who was much dejected lest she should not have breast milk. The learned professor ordered her some German milk powders (*magnesia calcinata*), and on the next day she had an abundant supply of milk; in fact, the state of her mind had arrested the lacteous secretion.

When powerful motives deprive the infant of normal or maternal lactation, its aliment must be supplied from other sources; and it remains to be determined whether a preference will be given to the milk of another woman or to that of inferior animals. The question is easily resolved. It must be admitted that breast milk approaches nearest to the object of nature, and that the stomach of a new born infant will more readily accommodate itself to aliment prepared by one of its own species, than of any other. It was well observed by Moss and others, that the gastric juice of the infant is best suited to act on the milk of its own species. Some writers, as

Baldini in Italy, Raulin, Dessassertz, and others in France, and Betzkey in Russia, preferred mercenary to maternal lactation; but there is no wet nurse equal to a healthful mother. When the parent is delicate and incapable of nursing, a wet nurse should be procured, if circumstances admit of it. But it is impossible to find one of the same age, the same temperament, the same state of health, or one who supplies the same quality of milk as the mother. The truth of this fact would be afflicting to parents and to medical practitioners, if every one's experience had not shown that infants do well on mercenary lactation, and that all wet nurses are not cruel step-mothers. "Happily," says Professor Capuron, "the greatest number, at a moderate remuneration, devote themselves with an astonishing generosity, to the well-being of their foster children; and even most of them, it must be remarked to their shame, are preferable to mothers." I cannot assent to the last part of this opinion, as there is no nurse to be compared to a healthful affectionate mother. It has long been observed by our profession that scarcely one wet nurse in a thousand takes proper care of her foster-child, or of her own child. Dr. John Clark well attested the bad consequences of mercenary lactation. "In some families," says that celebrated physician, "six, and in others eight, wet nurses had lost their own children." Commentaries on Diseases of Children. Dr. Merriman, in commenting on this observation, very humanely remarks, "if ladies who employ wet nurses were, in commiseration of the sufferings of their unhappy infants, so far to interfere in their behalf, as to insist on having them placed out under the care of sober, cleanly persons, and in open airy situations, and especially if they would refuse to take a woman whose child is very young, unless a wet nurse were procured to suckle it, they would be the means of preserving many lives, and of preventing much lingering suffering to these poor victims." A prodigious number of infants, committed to wet nurses, have their constitutions enfeebled, and are affected with rickets, deformities of the limbs, tumid abdomen, and most of them are destroyed before the fifth year of their existence. Nevertheless we observe some of the finest children reared by wet nurses. The chief cause of the great mortality of children is the ignorance of parents as to their management, because few indeed entertain correct notions as to aliment, clothing, bad effects of cold, exercise, rest, &c.

When the mother is incapable of suckling her infant, in consequence of the causes already mentioned, a wet nurse ought to be selected. The choice of such person is a matter of great importance; and one about which parents cannot be too particular. The best description of the qualifications of a wet nurse which I have seen is given by M. Cupuron, in fact it embraces every thing. It is the following:—

"It is necessary to attend to the age, constitution or temperament, her health, character, and morals, to her habitation, mode of life, and to the quantity and quality of her milk. We ought to take her from the age of twenty to thirty-five years, of a good constitution, of moderate embonpoint, that she be habitually healthful, and free from all disease, without apparent deformity, more brown than fair, and never red haired, that her mouth be furnished with good teeth, her gums firm, and in a good condition, her breath sweet, her breasts of an ordinary size, traversed by bluish veins, the areola a little prominent, the nipple well pierced, and of a convenient length. We ought to reject her whose skin is covered with eruptions, whose perspiration has a strong odour, she who has fluor albus, engorgement of the glands," &c. She should be of the same age, or nearly so, as the woman whose infant she undertakes to suckle, and she should be delivered as near the mother as possible. The milk of a woman who has been a nurse for six or eight months, becomes thick, white, and more caseous; and therefore more indigestible than that of a woman who has been recently delivered. Such milk will enfeeble the stomach, and this fact ought to be borne in mind when the infant is fed on cow's, goat's, or asses' milk.

Dr. Merriman questions the propriety of ladies procuring wet nurses who have been recently delivered. He says "he has seldom found the milk of such nurses answer so well as those whose children are eight or ten weeks old. They are not sufficiently recovered from the effects of parturition to undertake the duties generally required of a wet-nurse." Dr. Underwood is, however, of opinion, that the milk should be under six months old. It appears to me, that both these able writers have forgotten the simple fact, that women suckle from the hour of delivery, and with the greatest advantage to infants. It is also in strict accordance with physiology, that the milk which corresponds to the age of the infant is more easily digested than that which is much older. When the milk is too old it disagrees with the infant, and cannot be continued until the proper age for weaning.

Dr. Underwood has judiciously remarked, that the wet nurse should be sober, and rather averse to strong liquors, which young and healthful people seldom require in order to have plenty of milk. "She should be cleanly in her person, good tempered, careful, fond of children, and watchful in the night, or, at least, not liable to suffer in her health from being robbed of her sleep." She should likewise be active, sprightly, cheerful; not dull, stupid, fond of sleep, peevish, irritable, or morose; and she should reside in a pure air and salubrious situation. I cannot agree with this experienced physician, that she ought to be of a costive habit. No one in this habit is in perfect health; and therefore the comment of Dr. Merriman on the former author's text is good;—"Unless the bowels are re-

lived once plentifully every day the milk is rarely good in quantity or quality."

Women who offer themselves as wet nurses generally allow the milk to accumulate for some time before their examination by a medical practitioner; and by this proceeding the breasts will appear full in a woman who has a scanty secretion of milk. The state of her appearance and general health, and more especially the condition of her infant, enable us to form a correct judgment of her capability. When the milk disagrees with the infant it produces emaciation, griping depraved motions from the bowels, a frequent desire to evacuate the bladder, and, according to many, a host of other diseases, enumerated when describing maternal lactation. To these I shall direct your attention at the conclusion of my remarks on human lactation, before I describe "dry nursing," or artificial lactation. The wet nurse should suckle the infant for a few days before a final engagement is made with her.

The diet and regimen proper for wet nurses deserve attention. Most women err in supposing that they, while nursing, require more food than at other times. Nourishing aliment ought to be taken to satiety. The same rules as laid down for the diet and regimen of pregnant women should be observed by wet nurses. Those flesh meats which are most nutritious, with a moderate quantity of vegetables and ordinary drinks, are to be preferred. The wish and idiosyncrasy, or peculiarity of constitution, are the best guides with respect to the choice of foods. Whatever agrees with the mother generally agrees with the child. As a general precept, however, high seasoned, spiced, salted, and smoked meats, rancid bacon, pork, wild fowl, and cheese, ought to be avoided. Spirituous liquors, wines, ale, and porter, unless in moderate quantities, are highly dangerous; and we should recommend tea, coffee, chocolate, milk, broths, and plain soups, in preference. It is a general opinion among women, that porter increases the breast milk; and hence the custom among the middle and lower classes of society in this part of the United Kingdom, of taking two or three pints of this fluid daily. It is lamentable that every description of malt liquor is now so much adulterated and impregnated with some narcotic substance, that it proves injurious to the breast milk, and to the infant reared on it. I have known a vast number of respectable women, who had an abundance of breast milk, though they never tasted any description of malt liquor; nor do I agree with Underwood and others, that fluid of this description is a proper article of diet for suckling women. Those who are accustomed to it may take it in moderation; but it is impossible to lay down a rule as to the quantity for a proper daily allowance. Home-brewed unadulterated ale is a highly nutritious fluid, and is preferable to any other kind of malt liquor; but this is not easily procured, in consequence of the malt and other taxes against the salubrious beverage of the ancient Britons, the old and

invigorating *vinum Britannicum*. Dr. Struve, a celebrated German physician, recommended two parts of milk and one of well fermented beer, previously boiled "to rise over a gentle fire," to be taken cold, as a great restorative in cases of debility caused by lactation. He stated, that, in a short time, the strength was restored, and the milk increased. Some writers consider vegetable food peculiarly fit for nurses, as it rendered the milk more saccharine; and Dr. Underwood observed, that when vegetables, or even acids, agreed with the mother, healthful children rarely suffered. My own experience leads me to a different conclusion. I have often been called to children, who were very much griped, and the cause assigned was, that the mother had used esculent vegetables, such as cabbage, turnip, parsnip, carrot, &c. But I have also observed some of the finest and most vigorous children suckled by the Irish peasants, whose food was chiefly potato. M. Capuron is of opinion, that the taste and habit of the individual ought to be consulted more than theory and practice. This, like all general rules, is liable to objections, because some women, if guided by their inclination or taste, would select improper food. Exercise in the open air is indispensable to all persons for the preservation of health, but more particularly to wet nurses who have been previously accustomed to it, and whose health, as well as that of the infant, would be very much injured by close confinement in warm apartments.

A nurse should not be too sedentary, she can always take sufficient exercise in her house, and generally in the open air. With respect to sleep, the rule is, that the want of it, or broken rest, ruins the health, while too much prolonged, it enfeebles the constitution. A nurse requires eight hours' sleep during the first three months, even when the infant is healthful; and more than this, when it is delicate, or diseased, and disturbs her very frequently during the night. The bed should not be too hard or too soft, as either is injurious to health. The nurse should be allowed to live as she has been accustomed to do. A change from a plain diet, perhaps mostly vegetable, from a pure air, and daily exercise, if not hard labour, to a full diet of animal food, malt liquor, the close air of a large city, and a total want of exercise will seriously injure the nurse and the infant she nourishes. She should reside in an elevated situation in preference to that which is low, damp, or marshy. A western or southern aspect of residence is more salubrious than an eastern or northern. Finally, a wet nurse should be sound in mind and body, and of a cheerful and mild disposition, as well remarked by Rousseau, and "one newly delivered, whose constitution, both of body and mind, resembles the mother's as nearly as possible, provided that constitution be a good one."—Gregory's Comparative View of the State and Faculties of Man with those of the Animal World. Every precaution should be taken to prove that she has an attachment

for her foster child, and that she fulfils her duties towards it with zeal and humanity. The health and future happiness of the tender being committed to her care depend upon her attention and kindness; and for these she is morally responsible. Whenever the infant wastes under her care, if she cannot explain it as the effect of dentition, or teething, or other diseases, she ought to be discharged. If the child is constantly crying or screaming, it will become ruptured, affected with a sore throat, cramp, or dropsy of the brain. When, on the contrary, it is always asleep, it is under the influence of injurious soothing syrups, Dalby's carminative, Godfrey's cordial, diacodium, &c., it does not awake to take food, it wastes, languishes, and soon dies. In all cases, when the infant does not thrive, another nurse ought to be selected. Whenever it appears ill, feverish, or labouring under any complaint, the parents ought to be informed, or proper medical aid obtained. As a general rule, the less medicine an infant takes, unless when labouring under disease, the better. It is always ill when the motions from the bowels are of any colour but yellow.

In all possible cases, the wet nurse should reside in the house of the family whose child is under her care; because, when at her own home, she suckles her own infant, neglects both it and its foster brother, or may substitute one for the other.

If a woman is not in a fit condition to suckle her infant, she should follow it into the country, and there, in a salubrious situation, witness its progress, and assist in satisfying its wants.

The nurse, who fulfils her duty towards her foster child, ought not to be looked upon as a mere menial; the parents ought to show her gratitude and attention as the protector of their child. Parents in general forget this kindness, but when it is shown it creates an affection in the mind of the most illiterate nurse, which will never be effaced. It should ever be borne in mind, that the proper management of an infant secures a good constitution, while the opposite treatment induces delicacy, deformity, or diseases, and ensures a miserable existence. When the infant declines, after it it has been suckled by different women in succession, it ought to be removed into the country, adopting due precaution in making a selection of residence.

ANATOMICAL NOTES.

TUBERCLES.—FACTS ILLUSTRATIVE OF THEIR ORGANIC NATURE.

On the 26th of September, 1833, at the request of Mr. Fisher, surgeon of Cambridge, I injected, with size mingled with vermilion, the bronchial artery of the lungs of a woman, aged about 50 years, who had an exceedingly narrow chest, and who proved to have the upper

lobe of both lungs in a honeycomb state from numerous small abscesses, the consequences of tubercles, besides the other lobes sprinkled here and there in every direction, with tuberculous masses in every state of development, isolated and conglomerated, from one-third of a line to three and four lines in diameter, transparent, or more or less opaque, colourless, greyish, whitish, yellowish-white, or yellowish universally, or in the centre, or in concentric zones, the innermost being always more opaque and yellower than the outer laminae, caseous, pappy, or purulent, and in some cases softened only in the middle; also adhesions of the pleura by means of longer or shorter adventitious bands, but particularly more ancient and shorter in the vicinity of the upper lobes, and in the parts of them most riddled with crowded abscesses*, none of these abscesses having more than two-thirds of an inch in diameter, and all being lined with a transparent soft coat, surrounded in most cases with another skreiking under the scalpel; the left lung was injected by the bronchial tubes with strong alcohol, in the view of dilating the bronchial vesicles, and tracing their relation to the tuberculous masses and cavities. The right was examined in various sections next day, by the aid of a magnifying lens of about three-quarters of an inch focus. During the injection of the bronchial arteries, the coloured size came out through the trachea, and passed also into the pulmonary veins and arteries, and mingled in them with the half clotted blood they contained, thus clearly indicating in the first case, rupture into the open abscesses; in the second, direct connexion of the pulmonary artery and veins with the bronchial arteries†. In the lung, when examined, it was found that the adventitious membranes causing the adherence of the pleurae, were minutely injected‡ with the red matter, which in

* By abscesses here, I mean cavities, surrounded with a distinct lining membrane, containing more or less tuberculous matter, free and floating or attached to their walls, and matter having all the external characters of pus and mucus mingled together.

† A fact originally proved by injections, and delineated by the celebrated Raysh.

‡ By the word *injected*, throughout this paper, I mean traversed with vermilion

both cases had passed on from the adventitious membranes into the costal pleura; but was more apparent and in larger vessels in the recent than in the old adhesions. The injected vessels were traced through the substance of the parenchyme of the lungs, in the pleura pulmonalis, the posterior mediastinal cellular tissue, the bronchial glands, and even in the walls of the œsophagus, into the sub-mucous cellular tissue of the lower part of the trachea, of its bifurcation, and of its larger branches; and, indeed, in all those traceable; in the coats of most of the open and of all the unopened abscesses, as well as in the enveloping tissue of the isolated and conglomerate tuberculous masses, round which it was more abundant than in the parenchyme of the lungs generally. In no part of the parenchyme of the lungs was there found any effused injection; but in the centre of almost all the softened tuberculous masses, whether softened only in the middle or throughout, whether caseous, brain-like, or resembling pus, or chocolate and cream-like, there was more or less of the injection effused, while many of the opened abscesses were found filled with the effused injection. In no case was it found effused between the cyst and the surrounding parenchyme. In one open cavity, where a tuberculous mass, as yet unsoftened, and adherent to the cyst, presented the portion adjacent to the cyst still transparent and hard, and the portion nearest the centre of the cyst nearly caseous and yellow: both these portions were minutely traversed by injected vessels, but more particularly the caseous part. In all the walls of the cyst the injection was stellular, and similar to that seen through the mucous surfaces of the intestinal tube; several isolated tubercles in the first stage, without any surrounding thickening or apparent change of the pulmonary parenchyme, were traversed by injected vessels; while, in all the softened masses, whether there was effused injection towards the centre or not, injected vessels were traced, always most numerous successively from the circumference to the centre, and in proportion to the degree of softness*.

coloured branchings, having all the characters of the minute ramifications of vessels, and therefore presumed to be such.

* This is true only until such time as the

These facts, now confirmed by Mr. Fisher and Mr. Charles Linton, late of Guy's Hospital, entirely accord with the results of some made by me when at Edinburgh, when I injected the bronchial artery of the tuberculous lung of a cow and of a sheep, with an injection coloured with a finely levigated powder of ivory-black or bone charcoal, in order to prove, at the time when my friend Thomas Blundell was making his experiments for his thesis on melanosis, that appearances entirely similar to those in that state of the lung (now proved by his chemical analysis to be owing to a parenchymatal deposit of solid charcoal) might be produced by the injection of a thick solution of charcoal into the bronchial arteries. The tuberculous masses were injected in the same manner as in this last experiment, and the were then stated to the Royal Medical Society, and may be remembered by our esteemed morbid pathologist, Dr. Hope, who was then one of the ornaments of that Society, as he is now of his profession.

The important result to be deduced from these observations is, that tubercles are not inorganic masses. I may here state, also, that, in the softer masses, the vessels always came chiefly from some point of the walls of the envelope, in the form of a plexus, more abundantly than from the walls of the envelope generally; though this was also the case, all doubt of the injection and of the organic nature of the softer masses is removed by the fact, that of the effused matter being invariably found in the centre of the softer part of the mass, and never between the solid part of the mass and the envelope, for it certainly could not arrive at that centre unless it had found a vascular passage. I need scarcely point out the enormous importance of these simple experiments, which throw an entirely new light on the nature of tubercle. Suffice it to point out the facts, in the hope of eliciting more careful research in those who have spent so much of their lives in attempting to prove, theoretically, that tubercle differs from other morbid growths neither in its essential nor organic structure. I leave to Mr. Fisher the honour of explaining the results of these experiments,

soft pappy mass had taken on the different characters, and presented all the external forms of pus, or of pus mingled with blood.

by his interesting researches on this subject, hitherto, like cholera, the *opprobrium medicinae*.

Salle de Dissection de la Pitié,
Nov. 27th, 1833.

French Medicine.

Hydrophobia.—M. Buisson has written to the Paris Academy of Sciences, to claim a paper, which he forwarded so far back as 1823. The paper contained a case of hydrophobia, which was his own; the following is the report of it.

He had visited a woman, who had been suffering under symptoms of hydrophobia for three days. She had constriction of the throat, inability to swallow, abundant secretion of the saliva, and foaming at the mouth. She had been bit by a mad dog forty days previously; she was bled, and died shortly afterwards.

M Buisson, whose hands were covered with blood; incautiously cleansed them with a towel which had been used to wipe the mouth of the patient. He then had an ulceration upon one of his fingers, yet thought it sufficient to wash off the saliva that adhered with a little water. The ninth day after he was suddenly seized with a pain in his throat and eyes. The saliva was continually discharging into his mouth; the impression of a current of air, the sight of brilliant bodies, gave him a painful sensation; his body appeared to him so light, that he felt as though he could leap to a prodigious height, and experienced a wish to bite, not men, but animals and inanimate bodies. Finally, he drank with difficulty, and the sight of water was still more distressing to him than the pain in his throat. These symptoms recurred every five minutes, and it appeared to him as though the pain commenced in the affected finger, and extended thence up to the shoulder.

From the whole of the symptoms, he judged himself affected with hydrophobia, and resolved to terminate his life by stifling himself in a vapour bath. Having entered one for this purpose, he caused the heat to be raised to 42° (107° 36' Fah.), when he was equally surprised and delighted to find himself free from all complaint. He left the bathing-room well, dined heartily, and drank more than

usual. Since that time he has treated in the same manner more than eighty persons bitten, in four of whom the symptoms had declared themselves bad, and in no case has he failed, except in that of one child, seven years old, who died in the bath. The mode of treatment he recommends is, that the person bit should take a certain number of vapour baths (commonly called *Russeau*), and should induce every night a violent perspiration, by wrapping himself in flannels, and covering himself with a feather bed, the transpiration to be favoured by drinking plentifully of a warm decoction of sarsaparilla. M. Buisson declares himself so convinced of the efficacy of this treatment, that he will suffer himself to be inoculated with the disease, and as a proof of the utility of copious and continued perspiration he relates the following anecdote.

A relative of the musician Grétry was bitten by a mad dog, with many other persons, who all died of hydrophobia. For his part, feeling the first symptoms of the disease, he took to dauncing night and day, saying *that he wished to die gaily*. He recovered.

M. Buisson also draws attention to the fact, that the animals in whom this madness is most frequently found to develop itself spontaneously, are dogs, wolves, and foxes, which never perspire.

*** We are indebted for the above paper to the *Athenæum*, a journal which frequently contains the earliest and best accounts on all matters relating to science.

Italian Medicine.

On the use of the Trepan in Toothach.

THE means generally employed consist in the destruction of the nervous pulp of the tooth by laceration, cauterisation, or the application of caustic to the bottom of the carious tooth. Experience proves that it is only necessary to destroy the dental nerve to subdue at once all sensibility in the part. The means employed by M. Fattori, and which experience has proved to him is the best to be relied on, consist in the application of a small trepan on the diseased tooth, after having conveniently fixed the head of the patient. A few turns of the instrument are sufficient to perforate the osseous tissue of the tooth, and the extremity of the trepan immediately divides the nerve

which fills up the dental canal. The section made in this way immediately relieves the pain.

The operation, according to the old method of destroying the nerve with a sharp pointed instrument, seldom succeeded, as the caries rarely allowed of the easy introduction of the instrument into its cavity, and that it was also impossible to divide the nerve in many cases completely, besides causing the patient very severe pain at the time. The operation by the trepan, on the other hand, may be always relied upon, and removes every difficulty in the section of the nerve, as it is applied immediately over the part which the nerve traverses, and is certain of dividing it. The application of heat to the part is not a sure remedy, as the cauterisation must be very slight,—it gives out heat rapidly, and when applied to the part has only sufficient heat to burn deeply. Some have advised the direction of a flame of hydrogen gas on the part, but it is not necessary to dwell long on the uncertainty of such an application. In using the trephine, there is no risk of wounding any parts of the mouth near the affected tooth; when its application to those which are situated far back, near the ascending ramus of the lower jaw, is facilitated by the use of a *speculum oris*. In using caustic to the teeth, its application cannot be confined to the seat of the injury, and it spreads sometimes to the neighbouring healthy parts, causing an increased irritation of the dental nerve, and sometimes an inflammation of the tissue of the gums. Nothing of this kind can happen in using the trepan.

This remedy may be used successfully in all affections of the teeth, from whatever cause they may arise; and whilst many other remedial means lead on to the loss of the tooth, the trephine preserves it, in immediately relieving the pain, and preventing its return.

M. Fattori has found the trephine particularly useful in that affection of the teeth which he denominates *internal caries*, where the part is extremely painful, without showing the slightest appearance of alteration in its tissue. It is in such cases that the patient, having borne the pain for a considerable time, consents to the extraction of the tooth, which in being done is frequently broken off, and the fangs, which are often very painful, remain in the alveolar process. When relief does not

follow the application of the trephine, the pain which remains is frequently the result of antecedent inflammation in the neighbouring parts, requiring a particular treatment for its relief. It is advisable after the operation to fill the aperture made by the trephine with lead, to prevent any portions of aliment or other foreign substance from lodging in it, and becoming a fresh source of pain, by irritating the newly-incised nervous surface. This, however, should not be done until some days after the operation, when the parts shall have lost all their sensibility, and the irritation of the neighbouring parts is subdued. The application of the trephine is useful when old stumps of teeth, which cannot be removed, become painful; and, finally, it is exempt from all those accidents which attend the extraction of teeth.—*Arch. Gen. de Méd.*

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, December 7, 1833.

Professor BURNETT in the Chair.

Medical Reform.

MR. HUNT, Mr. Holt, Mr. King, Dr. Johnson, Dr. Sigmond, Mr. Griffith, Mr. Walker, Dr. Gregory, Dr. Leonard Stewart, and Dr. Fergusson, were the most prominent speakers on the abuses in the medical profession.

Dr. Gregory moved an amendment to the resolution that there ought to be one faculty;

“That in the opinion of this society, the evils, now complained of, will be remedied most effectually by the constitution of a central board of commissioners, which, under the sanction of the legislature, and the immediate direction of the Home Secretary, shall take cognizance of the medical education and practice in all its branches throughout the united kingdom, have jurisdiction over the several medical incorporations, and act as a court of appeal from their decisions.”

This amendment was lost, but its mover demanded a ballot, which is to take place at the next meeting.

We should apprehend that the profession has had quite enough of central boards and factory commissions, and certain are we that if the medical reform be made a government or cabinet measure, little will be done. We trust that Mr. Warburton and Mr. Hume will

never consent to such a proceeding. The medical profession is too powerful a body to be slighted by the legislature, and a parliamentary inquiry and discussion will alone satisfy its members. We are at a loss to know the reason that this country is the only one in Europe in which there is not one Faculty of Medicine and Surgery; and we see no difficulty in framing an act which would make the existing corporations, when purged of corruption, such a faculty. Every one knows that one of Sir R. Peel's bills repealed many more acts than the whole of those relating to the medical profession. The Academy of Medicine in Paris has arrived at the conclusion that all grades should be amalgamated, that the education should be much more extensive, and that officers of health should cease, and every medical practitioner should be a doctor in medicine and surgery.

MEDICAL SOCIETY OF LONDON.

Monday, December 9, 1833.

WILLIAM KINGDON, Esq. in the Chair.

Medical Reform.

THE whole time of the meeting was occupied in appointing a committee to prepare a petition to Parliament.

MEDICO-BOTANICAL SOCIETY OF LONDON.

Tuesday, December 10, 1833.

PROFESSOR BURNETT in the Chair.

DR. RYAN delivered a lecture on the efficacy of strychnine in hysteria, neuralgia, epilepsy, choleric diarrhoea, dyspepsia, and paralysis; and on the tonic effects of ilicine in dyspepsia. He related cases of hysteria, in which all the usual remedies had failed, and which were cured by strychnine. The dose was one-twelfth of a grain twice a-day, and, after some time, three or four times daily. The bowels were of course regulated before the employment of the medicine. The disease occurred from the age of puberty upwards, and some of the patients had ten fits a-day; these gradually diminished in number and violence, until they totally disappeared. The remedy proved highly beneficial in one case of epilepsy but failed in another. It was tried in a vast number of cases of diarrhoea during the

last autumn, and with astonishing success. The alvine dejections were sometimes of a rice-colour, but frequently as dark as tar; and Dr. R. had seen malignant cholera with blueness, though the fæces were of the latter hue. Some of the patients affected were relatives of individuals who had died of cholera, strychnine was extremely beneficial in cases of dyspepsia, complicated with hysteria in its various forms, a complication extremely common among dispensary patients. He combined the remedy with the compound rhubarb and colocynth pills, and administered it in the quantity already stated. His colleagues at St John's Dispensary had seen many of the cases to which he had alluded, and had employed the remedy themselves very extensively, and with the best effects. In neuralgia of the extremities it had afforded speedy relief. Hemiplegia yielded to it in three cases. Dr. Ryan considered its effects very different in small and large doses, and in no case was it urged beyond two grains daily. He had tried it in so many cases of disorders, purely nervous, that there was no day in which he did not prescribe it several times. He was anxious that the profession should give it a fair trial; and felt convinced, that it would, ere long, be generally employed. He had tried ilicine, and found it a powerful tonic.

Dr. Johnson remarked, that the remedy had been tried in opposite diseases, its sensible effects had not been described, it excited muscular action in paralysis, and it tranquillised it in hysteria. For his own part, the impression on his mind, from what Dr. Ryan had said, would be, that it cured all diseases in Cullen's Nosology.

Dr. Ryan observed in reply, that the reason he did not give a minute technical description of the disorders he mentioned was, that many of the members of the society did not belong to the medical profession, and therefore could not understand or take interest in medical disquisitions. He considered certain forms of hysteria, dyspepsia, and neuralgia purely nervous and belonging to the same class, and he had been misunderstood, if it was supposed that he recommended strychnine in all diseases. He had not observed its sensible effects, but the patients declared themselves better, and finally were discharged cured. He should like Dr. Johnson to describe the sensible effects of mercury, in alterative doses, in various dis-

eases, or of quinine or arsenic in ague, or of a dose of laudanum in curing colic.

Dr. Johnson rejoined, that mercury improved the secretions, quinine excited the circulation and caused a sensible improvement in both body and mind. Notwithstanding all that had been said, he considered strychnia a most dangerous remedy. In a case of hemiplegia, consequent to apoplexy, he had ordered a sixth of grain in three doses daily; the patient continued it for six days, and then he and the general practitioner were in consultation, when the subject of it expired suddenly, and he thought in consequence of the remedy. Unfortunately a post mortem examination was not allowed.

Dr. Sigmond observed, that it was extremely difficult to describe the sensible effects of medicines; and he could account for the discrepant declarations of the profession with regard to remedies. The fact is, that it is utterly impossible to obtain strychnine, or any other medicine, of the same quality from any two chemists or druggists, and this would be the case until there was medical reform. He had used strychnine in chorea, paralysis, and epilepsy, and certainly with good effects.

A gentleman described a case of hemiplegia of the right side, caused by apoplexy, in which he urged strychnine to three grains daily with the best effects.

The Chairman observed, that the effects of medicines varied on account of the cause assigned by Dr. Sigmond, and also on account of peculiarity of constitution. He instanced the discrepant histories of the upas tree as an illustration.

The time of the Society having expired, an adjournment took place to the 14th of January.

ROYAL SOCIETY.

THE two medals, offered by this society since his Majesty's accession, have been awarded to M. Decandolle, the celebrated botanist, and to Sir John Herschel.

Dr. Copland was elected a Fellow at the last meeting.

ROYAL DISPENSARY FOR DISEASES OF THE EAR.

At the annual general meeting of the governors of this institution, held on Thursday, it appeared, that since its establishment 8520 pa-

tients had been cured or relieved, including several cases of deaf and dumb. A vote of thanks was afterwards passed to Mr. Curtis, the surgeon and founder of the institution, for his humane and skilful attention to the patients, and it was resolved that a gold medal be presented to that gentleman at the next anniversary dinner.

NOTE FROM MR. SALMON.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Exclusive of various errors, there is an essential omission of part of a sentence, in the communication which you did me the favour of inserting, in your Journal of Saturday last. Your first mistake occurs at the eleventh line of the second column in the 583rd page, the monosyllable "an" being substituted for the words "*the most*." Your next error is at the forty-first line of the first column in the 584th page, the word "force" being printed instead of "*form*," which misprint recurs at the twenty-eighth line of the first column in the 586th page. In the fourth line of the first column of the 585th page, the word "able" is substituted for "*prepared*." A fifth mistake occurs at the nineteenth line in the second column at the 585th page, the word "there" being printed instead of "*here*." But the following omission is singular and important, as well as a material variation from the manuscript: at the fifty-eighth line of the second column in the last mentioned page, I am reported to have written "while circular fibres lie most commonly within reach of the finger;" the words of my manuscript are, "*while circular stricture will, from the redundancy of the circular fibres, be most commonly within reach of the finger*."

In justice to myself I request the correction of these mistakes through the insertion of this letter in the next number of your publication.

I am, Gentlemen,

Your obedient servant,

FREDERICK SALMON.

12, Old Broad-street,

Dec. 9th, 1833.

[We insert the above, as we deem it important that the exact words of Mr. Salmon should be given. In justice to ourselves, however, we must state, that, as a proof of the

article was sent to Mr. Salmon for correction, we felt satisfied that no errors could appear. We must also observe, that the charge of substituting "prepared" for "able," page 585, does not apply to us, as the sentence is printed in the same way in the *Lancet*.—Eds.]

THE LATE JOSHUA BROOKES, ESQ.

To the Editor of the *London Medical and Surgical Journal*.

GENTLEMEN,—I am requested by the Committee formed for the purpose of devising the most efficient means of erecting a monument, or a memorial, of the late Joshua Brookes, Esq. F.R.S., to announce, through the medium of your Journal, their wish of its being generally understood, that an Engraving of the late Professor is published, price One Guinea, the profits arising from the sale of which will be devoted to the above purpose; and subscriptions are also opened for the same object at the residence of each member of the Committee, and the Secretary, who respectfully solicit the aid of those members of the profession who may feel anxious to preserve some memorial of an eminently industrious and scientific anatomist.

J. C. CARPUE, Esq., F.R.S.,
Chairman.

H. S. Chinnock, Esq., Brompton
P. H. S. Colson, Esq., Goswell-road.
Robert Davey, Esq., Great Ormond-street.
H. Davies, M.D., Saville-street.
T. Fowkes, Esq., Mary-st., Regent's Park.
H. Hunt, Esq., 15, Lower Brooke-street.
Thomas Hodges, Esq., Gray's Inn Lane.
J. Johnson, M.D., Suffolk Place, Haymarket
J. Kendrick, Esq., 12, Manchester-street,
Manchester-square.
Thomas Litchfield, Esq., Twickenham.
J. Lavies, Esq., King-street, Great George-street, Westminster.
J. Malyn, Esq., 25, Duke-street, Westminster.
J. Nicholles, Esq., 35, Conduit-street.
J. T. Pettigrew, Esq. F.R.S., Saville-street.

Trusting that you will find room for the insertion of this in your valuable Journal,

I am, Gentlemen,

Your most obedient servant,

HENRY BENHAM.

13, *Middlesex Place, Lisson Grove*,

MEDICAL REFORM IN FRANCE.

PRACTICE OF MEDICINE AND PHARMACY SEPARATE.

*M. Agedum, sume hoc ptisanarium oryzae.
O. Quanti emte? M. Parvo. O. Quanti ergo?
Hor. Sat. 2, 3, 155.*

WE resume, with increased pleasure, our review of the Report upon Medical Reform in France, presented to the Academy of Medicine from its Committee by M. Double. That Report has been adopted by the Academy, with a few verbal amendments, and it is, by this time, to be found in the bureau of M. Guizot. Before the reading of the Report was concluded, the minister had addressed to the Academy a letter, expressing his approbation of its activity; he announced, that it was the intention of government to introduce a complete project of law upon the subject in the approaching session, and concluded with requesting the Academy to transmit to him its report by the end of the month (November), as he should regret being obliged to act without it. This is a sample of the spirit with which the French government has undertaken this important subject. The Faculty has also presented to the Minister a report, which concurs in all essential particulars with that of the Academy. In fact, the *Profession* in France seems agreed upon the necessary reforms; and there is little doubt that the Medical Association in Paris (a voluntary body) will approve of the conclusions of the Academy. MM. Orfila, Husson, Joly, Amussat, and Jules Guerin have been appointed a committee, to prepare its report.

This unanimity in the profession and energy in the government, warrant our conclusion, that many months will not elapse before the Medical Profession in France will be organised by law upon the basis of the report at present before us. One of our contemporaries consoles its frightened supporters by the cheering intimation, that it is confidently asserted the whole will end in no such great reform after all: bating the suppression of medical juries (the examiners, our readers will recollect, of the officers of health, or general practitioners in France), every thing else will remain in *statu quo*.

This, indeed, would be no great reform after all! We entertain very different expectations. We do, with much more consistency, agree with our contemporary in thinking, that the Academicians and the Faculty of France have displayed an earnestness and an ability worthy the reformers in a great nation; and we set the greater value on their labours, because, in the first place, in the deplorable condition of our Colleges and Universities, it is a mockery to expect the suggestion of any salutary reform from the organised heads of the profession in this country; and, in the next place, because, fortunately for the interests of medical reform at home, the very questions upon which the profession in France is now agreed, after mature deliberation,—touching equality of professional rank, uniformity of education, distinct practice of pharmacy,—must be debated, and receive their answer—yea or nay—before any reformation is attempted in our own medical organisation.

In truth, there are but two contending parties in France;—in one, we recognise those who have received a regular and extensive medical education, and who have devoted their time, their money, and their talents, to its acquisition. At

its head are naturally found every man of distinguished reputation in the profession—those who constitute the Academies and the Faculties; for there is no petty, jealous distinction among the educated practitioners in France. The other party—the second class of practitioners—whose pretension is ignorance, has no natural head. With us there may be said to be three contending parties. The great body of the properly educated medical practitioners are assailed, on the one hand, by a party claiming an equality of rights upon inferior qualifications, and too often carrying the arts of trade into the practice of a profession; and, on the other, they are pressed by the insulting prerogatives of a small but powerful body, which, standing isolated from the mass of the profession, possesses the strong holds of the Colleges and Universities. We advert to this distinction between the hostile parties of the two countries, since to us it exposes the folly, or the knavery, of those who expect any thing good to emanate from the Academies or Faculties of this country.

The report recommends the establishment by law of Departmental Medical Councils, in place of the Councils of Discipline. These institutions are to exercise a species of moral jurisdiction, by secret or public censure, over all the members of the profession, in their demeanour with regard to their patients or to each other; and to them are to be intrusted the important duties of enforcing, before the public tribunals, the law against quackery, “which is,” says the report, “to medicine, what hypocrisy is to morality.” They are to prepare lists of the persons qualified by diploma to practise; to examine the apothecaries’ shops; grant certificates of service to their apprentices; and, finally,

to collect all documents which may throw light upon the history of medical institutions or medical statistics.

From the decisions of these Councils, the accused may appeal to a council of superior revision, to be established in the capital, and ultimately he may seek the judgment of the *Cour Royale*.

To guard against the encroachments of the police, the report insists upon the absolute independence of the Councils; that they shall consist of nine members in the departments, and double that number in the capital; that doctors alone shall be eligible, but that every person subject to their jurisdiction shall have a voice in the election; that a third shall retire by seniority every three years, and shall not be eligible again till the subsequent three years.

Such are the general features of these institutions. In reviewing the arguments for their adoption, we feel pride in observing that the tone of medical ethics in this country must be much higher than in France. The instances among us of depraved moral conduct in a professional capacity are very rare; any breaches of decorum are sure to ruin the practice of the offender; and we do not foresee any necessity of legislation to correct these evils. The suppression of quackery can only be effectual, when the existing institutions are suited to the wants of society. Hence the inefficiency of the College of Physicians, in protecting the regular practitioner; hence the immunity with which quacks of all sorts violate the statute of the Apothecaries' Hall, whilst the ill-directed efforts of this latter body often assume the appearance of tyrannical persecution.

The report enters into an elaborate history of secret remedies, or quack medicines. In the first reforms after the French Revolution, these monstrosities

of medicine were altogether suppressed. For some unknown reasons, however, they were again revived, and have had since a precarious but very extensive existence. The Academy recommends their absolute suppression, or, at least, that they should be placed on the footing of patents, with this difference, that they should be subject to the previous approval of the Academy of Medicine; their sale to be confined to the apothecaries.

By these three great alterations, the establishment of a single order of medical men, the creation of Departmental Medical Councils, and the subjecting of quack medicines to the law of patents, the Committee expects the suppression of the greater number of the abuses committed in the practice of medicine. There are some, however, for which special legislation is necessary.

1. Dentists, oculists, &c., in fine, all who practice any branch of medicine, must possess the diploma of doctor.

2. "There are serious inconveniences," continues the Report, "in a medical man selling medicines, or in an apothecary practising medicine. The least is a *poly-pharmacy*, ruinous to the patient, and dangerous to science; without taking into consideration that medicine and pharmacy are sufficiently vast to occupy each an entire intellect, and cannot be cultivated at the same time with all the necessary care. It is not that we refuse to allow the medical man to procure himself to be admitted as an apothecary, and the reverse; it is the simultaneous practice of the two professions that we wish to proscribe."

It proposes, therefore, that none shall combine the practice of pharmacy and medicine, under a penalty of 10,000 francs (about 40*l.*), to be tripled for a second offence.

3. No doctor shall be allowed to make any agreement with an apothecary, nor derive any profit from the medicines he prescribes.

4. It seems a crime of a very daring character has been recently detected in France; the substitution of persons in passing the examinations for the degree of doctor. This is somewhat bolder than the false certificates which the College of Surgeons have lately denounced. Perhaps the laxity of the system of Inscriptions affords an opportunity for its commission. The report proposes an adequate punishment for its suppression.

5. No persons are to be admissible to any public medical functions without the necessary diploma.

6. No foreigner is to be allowed, by government, to practise until he shall have undergone the probationary acts before a Faculty.

7. By an article in the Code of Napoleon, the breach of professional secrets was punishable by fine and imprisonment, except in cases in which the law compels their disclosure. This exception is extremely offensive to the Medical Profession in France; as it was introduced, in fact, as a part of the imperial system of espionage: the Report, therefore, requires its abolition. In this country, a non-judicial breach of professional secrets is left to the laws of honour and good feeling. Our courts of justice will not allow the barrister or the attorney to give such secrets in evidence, but the medical practitioner is bound to communicate, before the public tribunals, every thing which comes to his knowledge in a professional capacity. This point has been long settled upon authority, although our judges have, at times, disapproved of the practice.

8. The irresponsibility of medical practitioners in the proper and conscientious

exercise of their judgment has been questioned in some of the inferior tribunals, which are to be found in France. The Report proposes to declare the law upon this subject. Some absurd distinctions, as to the right to recover fees, govern this branch of our law. A physician's fees should be as recoverable in a court of law as those of a surgeon, and he should be equally responsible for want of reasonable skill.

After demanding the abolition of the annual tax upon the practitioners of medicine, a tax to which no other liberal profession is liable, the Report recommends a codification in a single act of all the laws relating to medicine. This benefit we hope to enjoy by and by.

Among other regulations respecting the apothecaries, besides those which we have already given, it is proposed, that none shall be admitted as pupils, or apprentices, without the sanction of the general departmental councils, who shall inquire into the conduct and education of the candidates, and examine them in physics, mathematics, and natural history. The subsequent admission to the rank of an apothecary depends upon the Faculty of Pharmacy.

As it might be inconvenient in some parts of the country, to have a doctor's prescription prepared by an apothecary, it is proposed, that patients, who live at a certain distance from an apothecary's shop, shall be allowed to receive their remedies from their medical men.

The Report, in conclusion, recommends the publication of an Official Pharmacopœia, with such additions and alterations, from time to time, as the improved state of the science of medicine shall require.

Such are the principal heads of this excellent document. We shall return to the subject at another time, when we propose to canvass the schemes of Medical

Reform already broached among us, including that last novelty, the Central Board of Commissioners.

French Hospital Reports.

LA PITIE.

Paraplegia cured by Nux Vomica.

A GIRL, æt. 20, was admitted for a paraplegic weakness of the lower extremities; she had ready command over the muscles; but their energies were so feeble, that she could not walk, or even stand erect, but for a few minutes; the toes were in a constant state of extension, and upon any attempt to advance, the thighs bended upon the pelvis, the gait became unsteady and tottering, the feet crossed and became entwined with each other, and she would fall on the ground if not supported. This loss of power was most marked towards evening, and also during the periods of menstruation. The sensibility of the limbs was unaffected, and her constitution sound in other respects. The disease had commenced in her eleventh year.

The alcoholic extract of nux vomica was administered daily in an enema; the dose at first was two grains, and gradually raised to five, on the fourth day the power over the limbs was somewhat greater, and the catamenia were induced. Laterly the strychnine was given by the mouth in the form of pills, in doses of one-eighth, one-quarter, one-half, and two-thirds, of a grain. In two months and a half she was discharged cured.—*Arch. Gen.*

HOPITAL DE LA CHARITE.

Ossification of the valves and trunk of the Aorta.

A WOMAN, æt. 60, was admitted nearly in a dying state; she had ceased to menstruate at 50, and since that time had been repeatedly affected by a stifling sensation, accompanied with puffy swellings of the body. She had never had the venereal disease, nor ever taken mercury.

On the day after her admission she presented the following symptoms. Extremities cold and congested; slight general infiltration of the

subcutaneous cellular tissue; veins of the neck distended; orthopnœa; suffocation; difficulty in speech; refers her principal sufferings to her chest; percussion over the region of the heart gave no audible sound; the heart pulsed with rather more force than in its normal state; bruit de soufflet distinctly perceptible; pulsations regular, but could be scarcely felt at the wrist.

These symptoms were apparently diagnostic of contraction of the aortic valves, with hypertrophy of the heart. Although her symptoms taken entirely were of the worst kind, and the circulation through the system was principally of a venous character, it appeared highly requisite that her sufferings should be relieved. Fifteen leeches were applied over the region of the heart, pediluvia and maniluvia were prescribed, and the nitrate of potass was given internally.

On the following day she was somnolent, sub-apoplectic, and, with the exception of the palpitations, which were somewhat diminished, all her other symptoms were increased. The pulse was as on the previous day, nearly insensible. She died during the following night.

Autopsy.—There was a considerable quantity of yellow serum in each pleura, and some in the pericardium and peritoneum. The liver was enlarged, hardened, and altered in its structure; the subcutaneous cellular tissue was every where infiltrated; the skin was soft and flaccid, as in those who have been subject to anarsaca; the venous system was gorged.

The heart, which was of the size of two fists, nearly filled the entire distended pericardium; there was equal hypertrophy with dilatation in the four cavities; but the hypertrophy was more developed in the left ventricle, and the dilatation more prominent in the right. The blood which they contained was in soft black clots, like thickened jelly; their texture was but slightly adherent, and not fibrinous. On introducing the finger into the left ventricle there was found an obstruction at the aortic orifice.

This obstruction was caused by a considerable thickening of the three sigmoidal valves, which appeared fixed, but at a slight distance from each other, leaving between them but a chink or an irregular triangular opening, scarcely allowing a small pea to pass. They retained nothing of their natural form, mobi-

lity, or softness; they were hard, brittle, and calcareous.

Internally at the aortic opening, nothing abnormal presented itself. A few cartilaginous patches only presented themselves, but higher up the structural alterations were more evident. Immediately after giving off the brachiocephali, carotid, and left sub-clavicular trunks below an internal projection corresponding with the angle of reflection of the aorta, there was found on the inside of this vessel a small aneurismal dilatation, with alteration and ossification of the arterial tunics. Externally this formed a prominent tumour; internally a pouch nearly of a size to admit a large nut. Internally it was about one inch in diameter, its base was unequal, rough, and encrusted with ossifications, which became thicker towards its centre, at which point the excavation appeared deeper, and seemed to border still on some other part. On examining the external surface more minutely, a hard stalk was felt, which, on being deprived of the cellular tissue covering it, was found to be the artery itself, ossified, bounded on the one side by the aneurismal excavation, and on the other by the pulmonary artery, on slitting open which a little reddened depressed orifice showed the orifice of this diseased artery.

This last was ossified and obliterated for its whole length. Its thickness was about three-quarters of a line, and its length from six to eight lines. It was placed like an arch between the two arteries, and beneath the curve of the aorta from the point where it rose above the pulmonary artery to the central point of the aneurismal tumour.

The other circulatory vessels presented their normal appearance; the other parts of the body were not examined.—*Journ. Univ. et Heb.*

Italian Hospital Reports.

ROYAL HOSPITAL OF SANTA CHIARA,
PISA.

Encysted Abscess of the Cerebellum communicating outwards.

A SOLDIER, æt. 23, of a plethoric and healthy constitution, was admitted with the following symptoms, which had suddenly come on; active pyrexia, severe headach, stupor, hard vibrating pulse, &c. The left parotid was

swollen and inflamed. Active depletions speedily restored him; and all that he complained of was a deep-seated pain in the left ear, accompanied with tinnitus. Blisters and other topical means were tried, but to no purpose; he, therefore, left the hospital, but soon returned, when, in addition to the otalgia, there was a swelling of the meatus externus, and he was tormented with headach. By cupping, antimonial ointment, &c. he was relieved, and enjoyed a respite for several days, but it was only a respite, for his distresses soon came back, worse than ever; the headach was accompanied with violent pulsations, and a feeling of burning heat; the patient was feverish and watchful, and the integuments over the squamous bone were puffy and inflamed; leeches were applied to the inside of the nostril with considerable benefit, still there was the beating pain in the head, which at stated periods became much exacerbated. For about six days he was tolerably easy, but this deceitful calm was soon followed by another attack of sufferings, the swelling of the integuments had now increased, and pressure with the finger caused pain and left a pit.

These alternations of sufferings and relief, the distressing headach, which never altogether left the poor patient, and the immunity of the intellectual faculties led Dr. Scalvanti, of Pisa, (the narrator of the case) to predict disease of the cerebellum, according to the opinion announced by Lallemand, in his *Anatomical and Physiological Researches*. A doubt existed, whether the cerebellum was primarily diseased, or subsequently to a disease of the internal ear. However this might be, the man became worse, in spite of occasional intervals of a few days' ease; each attack was now severe and alarming; he became almost quite deaf and stupid, and the external swelling extended along the parietal and occipital bones. A surgeon, who was called in consultation, recommended an incision upon the mastoid process. He considered that the disease was altogether external, and that no suppuration of the cerebellum could have taken place, because there were no symptoms of compression, and the intellect was little impaired. He was not aware of the results of Lallemand's Researches. The incision was made, and the bone laid bare, but no appearance of disease was to be seen; the lips of the wound, however, were kept apart. The result seemed at first very grati-

lying; the headach and deafness were surprisingly relieved, and the external swelling much reduced. His physiognomy, however, became more stupid, and his speech betrayed a wavering state of mind. It is to be observed, that, during the intervals of ease, his appetite was always vigorous; unfortunately for himself he, on one occasion, had indulged to excess; he was seized with obstinate vomiting, became paralytic, and died on the 29th of June.

Dissection.—On cutting down to the bone, the temporal muscle was found to be healthy; the pericranium was somewhat thickened, and a spoonful of pus was found underneath it, between the squamous and zygomatic portions of the os temporis; a hole penetrated right through the bone, just above the meatus and the foramen externum. The membranes of the brain were highly injected; that portion of the left hemisphere, which occupies the middle and lateral fossa of the basis cranii, was very considerably increased in volume; the cerebral anfractuosities had disappeared, and the cerebral substance was unusually resistant and elastic; the dura mater was perforated opposite to the hole through the bone. Upon opening the lateral ventricles, it was observed that the left one was sensibly diminished in capacity, and right beneath it a sac, or cavity, of the size of a hen's egg, was found; the medullary substance had been wasted away, so that the boundaries of the sac were formed by the cortical, or grey portion, it terminated outwardly in a funnel-shaped prolongation, which communicated, by the previously mentioned apertures through the dura mater and the bone, with the abscess under the pericranium. The walls of the sac had a fibrous appearance, and altogether resembled an inflamed mucous membrane. The rest of the encephalon was normal.—*Annal. Univ.*

Portuguese Hospital Reports.

(Continued from page 605.)

Gun-shot wound of the Chest.

On the 17th of December, 800 Constitutionalists made a sortie across the Douro to remove wine from a store on the south side in the possession of the enemy. Before they completed the object of the sortie, the Miguelites came upon them in such torrents, as

made them rush into their boats in all the hurry and confusion of a desperate retreat. In crossing the river they became exposed to a galling fire of musketry; some of them, therefore, finding H.M.S. Orestes close to, sought her lee for protection. Our ship now found herself in the middle of a thick shower of musket-balls, and one of her crew (Mr. Connor) whose curiosity had induced him to disobey orders and expose himself, received a wound in his chest. The missile,—a large slug about one-third the size of a musket-ball, entered his chest a little below the left axilla, and lodged. When taken below he appeared a good deal alarmed; breathed with difficulty; pulse was frequent and feeble; complained greatly of oppression about his heart, and said he could feel the ball beating deep in his chest. By means of the stethoscope I found the respiration rather puerile in the right side, but obscure in the other. The action of the heart was not distinctly heard. Several times I heard most plainly the "metallic respiration." In about three hours after he received his wound, he breathed with so much difficulty, and was so restless, that we had fears of his instantly expiring, but a large bleeding had such a good effect that he began to feel almost well, and breathe almost easily. To be kept perfectly quiet, and abstain from food.

18th. Eight A.M. Slept more. Has pain in his chest, and has coughed up several times some florid blood. Pulse 105; breathing easy; skin natural. To be bled to faintness, to have an aperient draught, and to be kept as low as possible.

Eight P.M. Is much in the same state as this morning; has coughed up blood several times; has been freely bled; bowels purged twice; did not hear the "metallic respiration"; action of the heart remains obscure. Rigid abstinence to be continued.

19th. Eight A.M. Slept at intervals; cough slight; expectoration bloody; distressing hiccup; breathing pretty easy. No pain in chest, except on full inspiration, and then slight. Could not apply the stethoscope for noise, and can do that effectually only in the night.

Eight P.M. Complains very little to-night. Hiccup is the only distressing symptom. Heard the "metallic respiration," and also the "metallic tinkling" several times, and most distinctly. To continue the same ab-

sstinence, and to have a saline draught three times a day.

20th. Eight A. M. Slept badly; has great pain in the chest, more cough, and great difficulty of breathing; no particular thirst; pulse 110, but not strong. To be again bled to faintness, and draughts to be continued.

Eight P. M. Is much the same, though bled; blood neither cupped nor buffed; has not coughed up blood; did not hear the metallic respiration or tinkling. Continue the medicine. A blister to chest.

21st. Eight A. M. Slept badly, but feels better to-day than yesterday; has less pain in the chest, and breathes with much more ease. Pulse of a better character; bowels confined. To continue the saline draughts, and to have calomel gr. vj., jalap xij. immediately.

Eight P. M. Is much in the same state as this morning. Heard to-night more distinctly, and several times the "metallic respiration" and "tinkling."

From this moment he continued uninterruptedly to improve, so that at the end of about a month he was quite well. During the first three weeks of that period I heard distinctly and several times daily the "metallic respiration" and "tinkling." Not once did I hear the "metallic resonance." It might have existed and I not detect it for want of custom and delicacy of ear. The antiphlogistic system was observed throughout to a rigid extent. This individual is now in the Orestes in good health, which he has enjoyed since his recovery without the least interruption.

Hospital Reports.

MIDDLESEX HOSPITAL.

Fever.

FEVER, so called, one of the most common diseases in our metropolis, until of late years, did not meet with attention from English physicians at all equivalent to its importance. It was not until the scrutinising mind of Broussais, and the active mind of Clutterbuck, had directed attention to some *locale* as yet overlooked, that practitioners came to the bedside with any thing like rational views of this important disease. Before this era in medicine, the case-books abounded with putrid, pernicious, adynamic, and pituitous fevers, terms all denoting an entire ignorance of the subject.

But, important as is the gastro-enterite of

Broussais, and the cerebral affection of Clutterbuck, we are not to fix our attention too exclusively upon one particular organ. Happily for us, we may learn experience from the errors of great men; we may pluck the good and reject the evil of their theories; and, steering safely between Scylla and Charybdis, obtain a happy result of our labours.

Neither should the head, or the abdomen, or the chest, be exclusively attended to, but all parts claim an equal share in the consideration of the practitioner. The disease should not be treated for its name, as it often is, but its symptoms should be narrowly watched and judiciously combated as they arise in the progress of the disease; this, and this alone, is the mode by which we shall be enabled to discover the organ or organs affected, and the appropriate remedies for their cure. It is, however, sometimes a matter of no small difficulty to distinguish the seat of disease in fever. In some cases, all the symptoms are directed to the head, while the cause exists in the abdomen;—this fact is illustrated by the cases subjoined. It is, I think, pretty generally allowed, that by far the greater number of fevers are attended with intestinal disease.

I would suggest as an invariable rule, that those remedies, which are known to have a peculiar influence in arresting inflammation, and removing and repairing its effects, should be perseveringly and judiciously employed. I allude more particularly to mercury. The protoxide of that metal, in the form of hyd. c. cretâ, does appear to produce these effect more satisfactorily and with less disturbance to the general system than any other form which I have seen employed. But whilst we are arresting this inflammation, and necessarily reducing the system by the remedy, we must not forget, that we have at the same time to assist nature in repairing those destructions which have given rise to the disease. And this desirable end is not to be effected by general and powerful stimulants, as wine, brandy, &c., but the system is to be supported by animal broths, jellies, arrow-root, &c., at this critical stage of the disease. If it be necessary to administer stimulants, as it often indeed is, to rally the enfeebled powers, we must select them at the same time mild and diffusible, and thus, as it were, gradually to feel our way.

According to these principles the treatment

of fever requires nothing more than simplicity and vigilance on the part of the medical attendant; and experience shall declare it to be true, that the physician who thus combats fever will meet with a foe much less invincible than he who adopts the ancient method of practice.

Matilda Pole, a servant, æt. 19, admitted into the Middlesex Hospital, under the care of Dr. Wilson, Nov. 19th. Face flushed, skin dry, tongue clean, pulse 120, small. No pain in the abdomen; bowels open, stools natural in colour, but watery. Does not complain of any thing; has a disposition to sleep, almost amounting to stupor. Had rigors six days ago, with some sickness, attended with headache, and occasionally delirious at night.

Abkrat. cap. et applic. lotio frigida.

To be sponged with vinegar and water.

Calomel gr. v. nocte, et rep. mane.

20th. But little sleep; constantly moaning; no delirium. There is more stupor this morning; the tongue is disposed to be dry; pulse frequent, no strength, and occasionally irregular, so that it is counted with difficulty. The face on one side is intensely flushed, while the other side is pale and exsanguine. Bowels relaxed; no sickness; no pain in the abdomen.

Hyd. c. cretâ, gr. v. 6tis. Beef tea.

21st. Much in the same state; disposition to sleep the same, but she is quite collected when roused; tongue red, not quite so dry; a little pain on pressure in the cæcal region; slight cough; bowels frequently moved, motions the same; pulse much the same in character. The following day the purging increased, with no other marked alteration in the symptoms, and on the nurse going to the bedside to administer some beef tea, she found her dead.

Examination.

Head.—No morbid appearances detected in the brain. About 3j. of clear serum in the ventricles.

Chest.—Lungs merely congested; old adhesions in the left pleura.

Abdomen.—On examining the intestines no alteration was found until arriving at the lower third of the ilium. Here were observed a redness and vascularity of the coats, which in-

creased upon descending as far as the cæcum, where it gradually became fainter, until it assumed the natural appearances. The glands within the ilium were found, at the commencement of the vascular portion, to be elevated; lower down they were congregated so as to form round eminences, with a depression in the centre, and nearer to the cæcum they became more clustered, the edges being eaten away, more like chancres than any other form of ulcer.

The valve of the cæcum was studded with these excavations, some of which had perforated the two inner coats, leaving the external one thin and transparent. Noulceration was found beyond the valve.

Here and there were found evidences of the process of healing, the centre of some of these ulcers having been filled up, while the edges were rounded, instead of being ragged, as in the more recent ones.

Caroline Parkhurst, servant, æt. 16, admitted under Dr. Watson, October 22nd.

Countenance flushed; skin hot; pain in the temples; pulse frequent; tongue dry in the centre; thirst; bowels natural. Has had rigors and the usual symptoms of fevers for four or five days, sometimes with wandering at night.

Pil. calomel c. ant. gr. x, statim.

23rd. Complains of no pain, either in the head or abdomen. Pulse 90, full; tongue furred, moist only at the edges; bowels opened; stools presented nothing unnatural.

Calomel gr. iv, statim et post horas 3tis, haust. sennæ co.

24th. Has passed a bad night, wandering a good deal, and attempting to get out of bed when the nurse leaves her. She has also wandered during the morning. Pain in the head has returned; pulse small, and frequent; bowels open; stools watery; countenance intensely flushed, and the symptoms referable to the head.

Hyd. c. cretâ gr. v, nocte maneque,

Lotio frigid. capit. app.,

Hirudines viij, reg. cæci.

28th. Since the last report, there has been increase of purging, with pain in the cæcal region; stupor; flushed countenance; tongue dry; pulse frequent; no strength; restless nights.

Emp. canth. regioni cæci. Pil. hyd. c. creta. Beef tea.

30th. Considerably improved since the blister has been applied; the tongue is less dry; stupor diminishing. From this time she gradually approached to convalescence, and was discharged from the hospital Nov. 26th, quite well.

ST. GEORGE'S HOSPITAL.

Calculus Vesicae in the Female.

A LITTLE girl, aged 7 years, was admitted some time since, under the care of Mr. Brodie, with symptoms of stone in the bladder. The stone could be very easily detected, and, as the child's health was in a good state, the operation was performed on the 31st of October, a few days after her admission. Mr. Brodie made the following remarks on the case:—This operation, gentlemen, which you have just seen me perform, differs in many respects from the one which, until within these last few years, was performed in such cases. It was first mentioned to me by Mr Hodgson; it has been performed by Mr. Keate in this hospital, and also, I believe, by one of the surgeons to the Borough hospitals. You will all remember, gentlemen, that the old operation performed in such cases consisted in introducing a curved bistoury into the urethra, by which it was incised in its whole length, the incision being made on the side towards the left tuberosity of the ischium. After feeling for the stone with the finger in the bladder, a forceps was introduced along the incised urethra, by which the stone was seized and extracted. But I must mention to you that there was a very great and decided objection to the performance of this operation:—it led to one very serious and dangerous result, which was, that for ever afterwards the patient was afflicted with incontinence of urine, which could never be relieved or diminished by any treatment or line of practice which might be adopted for its relief. It is now, I suppose, nearly thirteen or fourteen years since I operated in this manner on a girl in this hospital; and even to this day, although she is now grown up to womanhood, she suffers from incontinence of urine, as the result of that operation.

The one you have just now seen me perform is this:—It consists, first, in introducing

such an instrument as this (*showing it*), so constructed as to allow a bistoury blade to be projected from its extremity, by which the membranous portion of the urethra may be incised to about an eighth of an inch. A Weiss's *dilatator urethrae* is then introduced, by which the urethra is dilated to a sufficient diameter to allow of the ready passage of the finger along its whole extent, and by which the stone in the bladder is fixed and seized with a pair of forceps and extracted. The reason why the membranous portion of the urethra is incised is, to allow of its being dilated with greater ease, which by this means may be sometimes done in two minutes; whereas by the other method, six, twelve, and twenty-four hours, and even sometimes two days were required. The operation proved completely successful; the child's health suffered but little; each day she continued to retain her urine for a longer period at a time, until gradually she lost all effects of incontinence of urine, and was discharged quite well.

Encysted Tumour of the Neck.

Oct. 25th, a child, æt. 2 years, was sent by Mr. Fuller to the Hospital to be examined by Mr. Brodie. A soft elastic tumour was perceptible on the left side of the neck, situated above and anterior to the carotid artery and external jugular vein. It was punctured with a needle, when a jet of straw-coloured fluid immediately issued from it, and the external diameter of the tumour appeared somewhat diminished. The child was placed on her father's lap, and Mr. Brodie cut into and along the course of the tumour, when a large portion of encysted cellular substance protruded, which was seized by the fingers of the operator, there being no forceps at hand; and, after some short delay, the whole of the cysts, about nine in number, and each containing a small portion of straw-coloured pellucid fluid, with the large external cyst containing them, were removed. A small artery was divided and secured during the operation, and great caution was necessary in avoiding wounding the external jugular vein. The edges of the incision were brought together by straps of adhesive plaster, and the child was sent to bed. Mr. Brodie remarked, with reference to this case, that it could not be looked upon as one of hydatids, but as a cel-

lular encysted tumour. He remarked, that he preferred the complete extirpation of such cysts to simply opening them and dressing them to the bottom with lint, as he had known one case treated according to the latter plan, in which such severe inflammation ensued, as nearly cost the patient his life. We may add, that the tumour was a congenital one, and its adhesions extended very far back to the transverse processes of some of the cervical vertebrae, rendering the tumour somewhat analogous to spina bifida. The child has gone on remarkably well without the occurrence of any bad symptom.

Clinical Remarks by Mr. Brodie.—Hemorrhoids and Prolapsus of the Rectum.

Mr. Brodie, after examining a man who had internal piles, made the following remarks:—This man, gentlemen, has, you see, internal piles; he has a bearing down of the fundament whenever he walks about, even for a few minutes, or goes to the water-closet. He says himself that the bowel comes down, and that every now and then it bleeds; and when protruded it is of the size of the tops of your two fingers, and therefore the affection is not of any new material importance. Now you will find that, in the majority of instances, patients who complain of a protrusion of the bowel have internal piles first, because these latter are very common, and secondly, because prolapsus of the rectum is very rare. Now, internal piles are very easily cured; if they are small they may be simply snipped off with a pair of scissors, or if not you may apply a ligature to them, tie them and then cut them off, and you will then see the course of the tortuous vein, filled with coagulated blood. This operation is a very simple one, and attended with so little danger, that out of two hundred cases in which I have performed it or seen it performed, I have only known one case die, and that was where the patient was in a very low debilitated state of health from bleeding, &c. Prolapsus of the rectum in adults is a very troublesome, and, I believe, incurable disease;—it is frequently accompanied or conjoined with internal piles; and if you separate the sides of the anal fissure, you will see the internal piles within the protruded bowel. Where prolapsus of the rectum depends upon this, if you cure the internal piles you cure the prolapsus; but in other cases the cure is very difficult, and if you push it up with your hand it will return again; and after it has lasted for some years, the patient becomes so accustomed to it, as to suffer but little inconvenience. Prolapsus of the rectum is a very common complaint in children, in whom the coats of the bowels are very thin and weak; in them the disease is very easily cured by the use of local astringent injections, and one of the best of these, which I have used, consists of one drachm of the muriated tincture of iron to one pint of water; by the use of this the disease can be very easily cured

and relieved. I have just looked over the remarks of M. Dupuytren on these subjects; and I believe myself, that what he has denominated prolapsus of the rectum is what I have called internal piles. It is very singular that in the country, practitioners seldom think of tying internal piles.

INGUINAL ANEURISM,

TREATED BY MR. BANNER, SURGEON TO THE LIVERPOOL HOSPITAL.

JAMES LIGHTON, æt. 32, was admitted a patient under Mr. Banner's care on the 27th of October, 1833, with inguinal aneurism.

History.—At the latter end of June last, whilst striking with a heavy hammer, his occupation being that of striker in an iron foundry, he felt a sudden pain in the groin and top part of the left thigh; the pain did not incapacitate him from work, and it was not until going to bed on the night of the accident that he felt a small tumour. He resumed his work on the following morning, and continued it daily until the middle of September, when the limb began to swell, and became painful; he had rested from work until the beginning of October, and had occasionally taken Epsom salts.

Appearances.—There is considerable swelling and discolouration of the whole leg; there is a pulsating tumour situated about an inch below Poupart's ligament, of the size of a hen's egg, though not very elevated, a large portion of which can be dispersed by pressure, which on being removed resumes its original bulk; there is an enlarged gland situated above the aneurism, between it and Poupart's ligament. On applying the ear to the tumour there is the bellows sound. The health is good; nor has he had any affection of the heart, or other disease that he remembers.

Treatment.—A teaspoonful of the sulphate of magnesia every morning in water; spirit wash applied constantly to the part; the patient to be kept in the horizontal position, with the leg bent and placed on a pillow. A consultation was held by the surgeons of the hospital, Mr. Gill and Mr. Wainwright, when it was considered proper to recommend the operation for tying the external iliac. Mr. Banner accordingly performed the operation on the 14th of October.

Operation.—An incision was made, commencing about half an inch on the outside and a little above the external ring, which was carried down to the edge of Poupart's ligament, and continued on in the direction of the anterior superior spinous process of the ilium, forming a semilunar cut of about two inches and a half in length; the tendon of the external oblique was exposed the whole length of this incision, and cut through; the spermatic cord was traced to the transverse fascia. On introducing the finger here, the pulsation of the external iliac artery could be

easily felt; the opening in the transverse fascia was enlarged by the fingers, so as to expose the artery; with the aid of a sharp pointed probe, the sheath was torn so as to allow the point of the finger to pass from within under the artery, which was done by an assistant raising the leg, and pressing the thigh forward. A common aneurism needle, armed with a ligature composed of three silks, was passed on the finger under the artery, and tied so as completely to stop all pulsation in the tumour.

The edges of the wound were drawn together with adhesive plaster, and slight pressure used. The patient was removed to bed, the leg was placed on a pillow in the bent position, and hot flannel applied to it.

After treatment.—Six hours after the operation the patient became restless, and complained of soreness of the part and great thirst; the pulse was at 90, full, and strong; the tongue slightly furred and dry; the limb was warmer than its fellow. Eight ounces of blood were taken from the arm. Low diet.

2nd day. He has passed a very restless night, complains of an aching pain in the knee, extending to the foot; the soreness in the wound continues; the pulse is at 90 and full; bowels have not been acted on since the operation. V. S. ad $\frac{3}{4}$ x.

A tablespoonful of castor oil to be taken soon, and the leg to be folded in flannel; the remaining treatment consisted in keeping the bowels acted on with castor oil. The limb remained of a comfortable heat throughout the cure. On the 16th day the ligature came away; on the 18th he was carried home; on the 21st he was able to walk about.

Nov. 20th. He walked to Mr. Banner's house and back, a distance of two miles. The wound is quite healed, with the exception of a small portion, through which the ligature passed. He complains of weakness in the left leg, and oedematous swellings at night.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, December 5th.

S. B. L. Bell	. . . Falmouth.

OBITUARY.

BARON BOYER.

This renowned individual died on the 22nd ult. He was the oldest surgeon in Paris. He ordered, in his will, that his funeral should be private, and that no funeral oration be delivered over his remains.

ILLNESS OF BARON DUPUYTREN.

THE celebrated Dupuytren has been seized with paralysis of one side, and is consequently incapacitated as an operator and lecturer.

We are happy to inform our readers that Dr. Paris is much better.

LITERARY INTELLIGENCE.

SHORTLY will be published *Outlines of Comparative Anatomy.* By PROFESSOR GRANT, M.D. 1 vol. 8vo. with Engravings.

Shortly will be published an enlarged Edition of a Treatise on the Blood, which was left in an unfinished state by the late C. F. THACKRAH, Esq., of Leeds, completed and edited by THOMAS G. WRIGHT, M.D. To which will be subjoined a short Memoir of the Author.

In the Press, the *Physiology and Treatment of Asphyxia.* By JAMES KAY, M.D., formerly President of the Royal Medical Society of Edinburgh, &c.

BOOKS.

MONOGRAPHIE des Dermatoses, ou Précis Théoriques et Pratique des Maladies de la Peau. Par M. le BARON ALIBERT, Médecin en chef de l'Hôpital Saint Louis, &c. &c. A Paris, chez le Dr. Daynac, Editeur, Rue de Bac. 1832.

First Lecture of the Course on Comparative Anatomy. Delivered in the Theatre of the Royal College of Surgeons by A. JACOB, M.D. Dublin: Hodges and Smith. 1833.

Observations and Suggestions on the Arrangement of the Maryborough District Lunatic Asylum. By JOHN JACOB, M.D., &c., &c. Dublin: Dixon and Hardy. 1833.

No XII. of the Liverpool Medical Gazette. Edited by DR. HUNTER LANE.

Introductory Lecture to the Practice of Physic, at the opening of the Eccles-street School of Medicine and Surgery. By WILLIAM STOKES, M.D., &c., &c., &c. Dublin: Davis Webb. 1833.

Part the First, of a Critical Inquiry into the various Opinions advanced on the Physiology of the Blood-Vessels, Absorbents and Process of Absorption in the Adult and Fœtus. By RICHARD VINES, Demonstrator of Anatomy at the Royal Veterinary College. London: Longman and Co. 1833.

CORRESPONDENTS.

Melampus.—The poem is good, but our sober readers would object to it.

H. W. R.—We are obliged for the lecture, and shall be happy to publish it and others from the same quarter.

Dr. Thomson's reply to Mr. Wallace in our next.

Dr. Ryan has removed to 4, Great Queen-street, St. James's Park, Westminster.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

No. 99.

SATURDAY, DECEMBER 21, 1833.

Vol. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,**Session 1832—1833.*

LECTURE LXVIII., DELIVERED MARCH 14, 1833.

GENTLEMEN,—Every consideration which I have been able to give to the subject of the venereal disease, leads me to believe, that the complaint has existed from time immemorial; that it always has existed, and always will exist in every populous country, where promiscuous sexual intercourse takes place. Those who ascribe the origin of syphilis to the latter part of the fifteenth century, have been much influenced by one fact, which is, that down to that period no description of any disease, corresponding exactly to what we call syphilis, had been given by medical writers; and although ulcerations on the genitals and buboes had been commonly treated of, no mention was made of the secondary symptoms, no connexion was ever traced, or even suspected, between the primary effects, as they are called, and the sore throat, cutaneous affections, and the pain and swellings of the bones, which we denominate secondary ones. Perhaps, however, it is scarcely allowable to infer, that because no notice is taken of the secondary symptoms of the venereal disease in the old works on medicine and surgery, that such complaints were not in existence previously to the close of the fifteenth century. The relation of the primary and secondary symptoms to one another might have been overlooked; it might never have been suspected when there had been a chancre on the penis, that the sore throat, cutaneous affection, or node, which came on subsequently, had any connexion with the sore. Certainly this will not seem incredible, when you recollect, that it was not until a very recent date, that some particular effects of the venereal disease were made out; and that, even at the present day, with all the

advantages of a better system of pathology, our knowledge of many circumstances, relative to this extraordinary disease, is very obscure and uncertain. Thus, two or three hundred years hence, when it shall be recorded to posterity that at as late a period as the year 1800, no account had been given of syphilitic iritis, and that the true character of gonorrhoeal ophthalmia had not been described, I think it would not be correct to infer, that those affections had had no existence until the time when they began to be discussed in works on surgery. Their not having prevailed, and their not having been described, are two different things.

Gentlemen, let me call your attention to the fact, that not only are diseases of the genitals acknowledged to have existed from time immemorial, but we have every ground for believing, that they were of a contagious nature. This seems proved by the precautions adopted by various governments, to prevent the extension of such disorders among the population. No doubt you have all heard, that in the borough of Southwark, there were formerly places called *stews*, where prostitutes were confined, and received the benefit of surgical assistance. They were taken up, and put into these establishments, whether agreeable to them or not, by virtue of certain decrees, made expressly to protect the rest of the community from the risk of catching their complaints. These institutions, in which the unfortunate young ladies were prepared for service again, were oddly enough placed under the supreme management of the Bishop of Winchester, which appears to me to have been at all events a most whimsical arrangement. (*a laugh*.) All this happened, you will observe, prior to the supposed origin of the venereal disease. At the same time, or even earlier, similar establishments were formed at Paris, Edinburgh, and especially at Avignon, where a brothel or stew was established by Joana, the queen of the two Sicilies; a young queen, too, who must have had a most tender regard for the health of her subjects, such a regard as made her think of some matters, not exactly, perhaps, within the province of female delicacy and modesty. (*a laugh*.) But, gentlemen, you may well

laugh, when you hear, that in the holy city of Rome, a stew or brothel was actually established under the pope's nose, under the walls of the Vatican itself, with an abbess at the head of it; and this at an earlier period than the time, when such institutions originated in Edinburgh, Paris, and London. Whoever hears these facts, I think, cannot possibly doubt, that a contagious disease of the genitals existed before the period often fixed upon as the date of the origin of the venereal disease; and at all events, you may conclude, that previously to the year 1493 or 1494, the world was not altogether such a model of innocence as it was in the days of Adam and Eve. (*a laugh.*)

You will understand, gentlemen, from the statements which have been made, that the generally received doctrine, respecting the venereal disease, is, that it is transmitted from one human being to another by means of a specific morbid, or morbidic, poison (the latter term is the more correct one), which, when applied to the skin of a person in health, is apt to produce inflammation, suppuration, and ulceration, and that the discharge secreted by the first sore, or by the nearest bubo to it, has the property of communicating the disease by contact or inoculation; and that, with the exception of the mode in which the foetus in utero may be infected, pus, or some other discharge, is always the medium, by which the poison is communicated from one human being to another. We know nothing about the venereal poison in a separate form; we are ignorant of its chemical and general properties; we know nothing about its colour, consistence, or look; we only recognise it as combined with a purulent secretion; and judge that it is a poison, by its action on the human body. It produces not only *certain local effects*, or *primary symptoms*, but also *constitutional effects*, or, as they are termed, *secondary symptoms*, arising after, and in consequence of, the entrance of the poison into the circulation. Excepting the human race, no animal is susceptible of the venereal disease. You may inoculate a dog, a cow, a horse, or other animal with matter taken from a chancre or bubo, and you will find, that the disease will not be communicated. This fact warrants the conclusion, that the poison must have been produced in the human species, to which its effects are restricted. It seems also probable, that it was first formed on the genital organs; for, if it had begun in any other situation, it would probably have been confined to the unfortunate individual in whom it originated; it could not well have been communicated to any other person; because, as John Hunter observes, sexual intercourse is the only natural connection between one human being and another, except that which prevails between the mother and the child.

But, gentlemen, respecting this part of the subject, I think the question might very well be asked, is it rational to suppose, that all the

syphilitic mischief, that has scourged the various cities, kingdoms, and generations of the world, has arisen from the amours of one unlucky individual, in whom the virus was first produced? Are we to fancy that the disease never had but one primary source? and that it is to the mysterious concoction of the specific virus by a single individual, that all quarters of the world, and all generations, are under obligations for the gift of the venereal disease. No doubt syphilis must have had a beginning, like every thing else; but probably it has had numerous beginnings. Various considerations would lead us to expect (what is indeed the fact) that, in every country, where the population is numerous, and promiscuous sexual intercourse exists, the venereal disease would be very prevalent. I was not therefore surprised to find, that Mr. Travers in a late publication has expressed his conviction, that, if all the syphilis in the world were now to be annihilated, a never-failing source of the disease would still remain in the action of the matter of superficial or gonorrhoeal ulcers of the penis on the human constitution. If I have a correct recollection of this gentleman's views, however, he looks upon the poison of syphilis and that of gonorrhoea as identical, and the sentiment, which I have quoted from his interesting remarks on the pathology of the venereal disease, perhaps, necessarily involves that conclusion; but I ought to tell you, that the point is a disputed one, and, that the greater number of professional men do not subscribe to such an opinion.

I have explained, that the venereal disease is commonly believed to be communicable only through the medium of pus. The late Mr. Hey, of Leeds, was induced, however, to regard this doctrine as incorrect; and, from some cases, which came under his observation, he suspected that the disease might sometimes be communicated, not only after all ulceration and suppuration had ceased, but even when the person, giving it to another, was to all appearance in perfect health; but whoever reads the cases on which Mr. Hey founded this extraordinary inference, will perceive how great was the possibility of his being deceived by the patients, who gave him the histories of their cases. Some particulars involved the honour of the individuals themselves, and therefore they might have been ashamed of disclosing every secret relative to their cases. It is more rational, I think, to suppose that Mr. Hey had been deceived by the patients themselves, than that any such mysterious sources of infection existed, as those implied by his view of their cases. The idea that syphilis can be communicated by a person so healthy, that he has no venereal matter formed upon any part of the surface of his body, or indeed any visible or palpable complaint whatsoever, is a problem, that every thing yet ascertained about the nature of syphilis tends to refute. It is frequently thought that the venereal disease may be transmitted from the mother to the foetus through the

medium of the blood, and there is no doubt that the case is so. In consequence of this fact many surgeons have been inclined to suspect, that as the disease is communicable through the medium of the blood, it may be also communicable through the medium of the natural secretions such as the saliva, the semen, the milk, &c. With respect to the fœtus, we may infer that it receives the infection by means of the circulating blood, in the same manner as the mother herself receives her secondary symptoms; but with regard to the saliva, semen, and milk, it is difficult to pronounce how far these secretions will serve as means for the transmission of the disease, till the powers of the secondary symptoms in general to do so is better made out. I believe with Mr. Travers, that none of the natural secretions of a contaminated individual can communicate the disease to other persons. The following statement in this gentleman's work is interesting; a man, who has syphilis in the secondary form, provided he be free from all affections of the genitals, will communicate no taint to his progeny, any more than to his wife; but a healthy wet nurse, getting a sore nipple in consequence of suckling a pocky child, (a child, I presume, that has contracted the disease from the diseased state of the mother's pudenda at the time of her confinement,) and having secondary symptoms, will communicate the disease to the fœtus of which she may become pregnant. Now you will recollect, that this is agreeable to the usually received opinions, that the blood will contaminate the embryo, though all genital sores may be absent, and though the party cohabiting with the woman, is beyond the sphere of the influence of the disease in her. As far as the present state of our knowledge of the subject reaches, we may conclude, that the disease is only communicable through the medium of purulent fluid, and not an ordinary secretion, with the exception of the mode of its transmission to the fœtus, which receives the infection through the circulation, and may be regarded as under the same circumstances, with respect to the secondary effects of the disorder, as the mother herself. Of the disease in new-born children, I shall hereafter speak more particularly.

The effects of the venereal disease are different in different individuals; two men may have connexion with the same woman; both may catch the disease, but one will have it severely, and the other only in a slight and mild form. One man has been known to give the disease to different women; some of whom have had it in a lenient shape, while the others have suffered most severely. Sometimes the same individual will have two or more sores of different kinds at the same time. In some examples, you will see sores of the Hunterian character on the glans penis, while sores of other descriptions are close by them. One of the most curious circumstances in the venereal disease is not unfrequently exemplified in the army: soldiers are well known to be gregarious in their amours: a party of six or eight will have connexion, one after another, with the same woman (*laughter*). In this manner, several men sometimes contract disease from the same source, and on one and the same occasion. Certainly it is highly disgraceful that such things should be, as they manifest a degradation of moral feeling hardly consistent with civilisation. Men of these depraved habits frequently all get wounded together, as a kind of reward for their want of decency; but they are not all wounded in the same manner; some will have sores of one kind; some will catch sores of another description; some will have both sorts of ulcers; and others will contract a discharge from the urethra. These facts are adverse to the opinion, that syphilis is owing to a plurality of poisons; for here are many different effects, apparently produced from the same source. Facts of this nature create considerable difficulty in the investigation of syphilis,—a difficulty that cannot be solved by reference to peculiarities of constitution or states of health; for certainly no explanation on these principles will account for two or three different kind of sores occurring in the same individual on the same part, and all at the same time. Neither can the circumstances be ascribed to the differences of texture between the prepuce, glans, and corona glandis. No doubt, the kind of texture often modifies the appearances of sores; but this is a fact that will not explain the peculiarities I have mentioned, because you find sores of different kinds on one and the same texture; as, for instance, on the prepuce, or on other parts of the skin of the penis. However, before any inference to be depended upon can be drawn from the circumstances mentioned with respect to these licentious soldiers, a very minute investigation into their cases would be essential; for it is hardly to be credited, that such individuals would not be in the custom of cohabiting with a great number of women in a short space of time, and not merely with the one who received them in a gregarious way. But, notwithstanding our inability to explain the facts I have specified, by any reference to constitution and climate, do not suppose that these agents have no influence in modifying the effects of the venereal disease; for it is well known, that syphilitic affections get well with greater facility in warm climates, and that the symptoms are much milder there than in cold countries. The observations made by Dr. Ferguson on the venereal disease in Portugal and the West Indies, leave no doubt on these points. We learn from a valuable paper, which he published in the *Medico-Chirurgical Transactions* some years ago, that, at the time when the British army was in Portugal, our soldiers there suffered severely from this disease; yet the natives, from whom they caught it, had it in an exceedingly mild form; so that, while amongst our troops it made terrible ravages, occasioning in many of them the

gregarious in their amours: a party of six or eight will have connexion, one after another, with the same woman (*laughter*). In this manner, several men sometimes contract disease from the same source, and on one and the same occasion. Certainly it is highly disgraceful that such things should be, as they manifest a degradation of moral feeling hardly consistent with civilisation. Men of these depraved habits frequently all get wounded together, as a kind of reward for their want of decency; but they are not all wounded in the same manner; some will have sores of one kind; some will catch sores of another description; some will have both sorts of ulcers; and others will contract a discharge from the urethra. These facts are adverse to the opinion, that syphilis is owing to a plurality of poisons; for here are many different effects, apparently produced from the same source. Facts of this nature create considerable difficulty in the investigation of syphilis,—a difficulty that cannot be solved by reference to peculiarities of constitution or states of health; for certainly no explanation on these principles will account for two or three different kind of sores occurring in the same individual on the same part, and all at the same time. Neither can the circumstances be ascribed to the differences of texture between the prepuce, glans, and corona glandis. No doubt, the kind of texture often modifies the appearances of sores; but this is a fact that will not explain the peculiarities I have mentioned, because you find sores of different kinds on one and the same texture; as, for instance, on the prepuce, or on other parts of the skin of the penis. However, before any inference to be depended upon can be drawn from the circumstances mentioned with respect to these licentious soldiers, a very minute investigation into their cases would be essential; for it is hardly to be credited, that such individuals would not be in the custom of cohabiting with a great number of women in a short space of time, and not merely with the one who received them in a gregarious way. But, notwithstanding our inability to explain the facts I have specified, by any reference to constitution and climate, do not suppose that these agents have no influence in modifying the effects of the venereal disease; for it is well known, that syphilitic affections get well with greater facility in warm climates, and that the symptoms are much milder there than in cold countries. The observations made by Dr. Ferguson on the venereal disease in Portugal and the West Indies, leave no doubt on these points. We learn from a valuable paper, which he published in the *Medico-Chirurgical Transactions* some years ago, that, at the time when the British army was in Portugal, our soldiers there suffered severely from this disease; yet the natives, from whom they caught it, had it in an exceedingly mild form; so that, while amongst our troops it made terrible ravages, occasioning in many of them the

worst of mutilations, the natives suffered but very slightly, and got well under what would here be regarded as inert treatment. Attempts have indeed been made to explain these facts by the greater excesses which our soldiers were guilty of, and their habit of drinking more spirits and wine than the Portuguese; and, no doubt, these circumstances must have had some share in rendering the disease worse in them than in the more abstemious natives. Another question is, whether the greater mildness of the symptoms of the venereal disease in warm than in other countries, is to be ascribed to any modifications or changes in the nature of the poison, produced by the temperature or atmospheric causes? I think what has already been stated to you will refute this notion; for you hear that in Portugal the British soldiers suffered severely from the disease; consequently, the virus must have possessed sufficient activity, provided the ravages alluded to were truly occasioned by the operation of the virus, and not by phagedenic diseases, independent of such a cause. Another question is, whether the greater mildness of the disease in warm countries is owing to the effects of the atmosphere in rendering the individual less susceptible of the influence of the disease; or whether it maintains the system in such a state as makes the disease yield more readily to the remedies employed. All these points are still disputed ones. The opinion that the disease is continually getting milder and milder, and will in the end cease altogether, has been entertained almost from the earliest periods; at all events, nearly from the time of its supposed origin, towards the close of the fifteenth century; but, instead of adopting this conjecture, a more rational way of explaining its greater mildness at the present day will naturally suggest itself to every man of judgment and reflection; viz., by the consideration of its treatment being now conducted with much greater skill and discrimination than it was forty or fifty years ago. Many, who incline to the opinion that the disease originated towards the close of the 15th century, lean also to the belief, that the disease is continually changing its nature, and becoming milder; for if they did not shape their conclusions in this manner, they would be obliged to renounce the other doctrine, respecting the time of the first origin of syphilis; because, as I explained to you in the last lecture, the venereal disease of the present time is totally different from the rapidly fatal and infectious disorder which broke out in the French army before Naples. As a matter of course, therefore, they must think that syphilis has changed its nature, and assumed milder forms. Within my recollection, the disease was more severe than it is now; but the cause of this fact I should account for on a different principle, because, when I was a student at St. Bartholomew's Hospital, the treatment of this disease was what would now be considered injurious in the extreme, for it

consisted in the administration of mercury in the most unmerciful and indiscriminate manner. The practice in those days was founded, indeed, on a doctrine that is now exploded. One of the principal mistakes of the old surgeons arose from the supposition, that it is the invariable character of syphilis to proceed from bad to worse, unless checked by the power of mercury. This was undoubtedly a most pernicious doctrine—one that led to the death of many unfortunate persons. When Mr. Abernethy was making investigations into the nature of the venereal disease, he went round to all the most experienced hospital surgeons in London, and put these questions to them—whether the venereal disease is curable without mercury? whether the primary symptoms can be removed and the disease be permanently cured without the aid of that mineral? and from all these men of eminence he received the answer, that a spontaneous cure, or even one without mercury, was totally impossible. So much for the blindness created by old prejudices handed over from one surgeon to another—prejudices which annihilate all the advantage of great opportunities of observation. In those days, then, the opinion prevailed universally, that the disease would be sure to extend itself, and could not possibly admit of a salutary change, unless the patient were put under the influence of mercury. However, in the year 1813, in one of the early editions of my *First Lines of Surgery*, I happened to take into consideration some observations inserted by the late Mr. Pearson in his *Treatise on the Effects of Certain Articles of the Materia Medica in the Cure of Lues Venerea*, and from which it clearly appeared to me, that what he stated was absolutely equivalent to an admission, that syphilis would sometimes, at least, get well under the administration of the most inert medicines. Although this gentleman, whose experience at the Lock Hospital was unbounded, may be said to have added the weight of his authority to the maintenance of all the principal Hunterian doctrines relative to syphilis, any impartial man who studied his book could not fail to discern the clear admission in it, that a beneficial change was often brought about, in syphilitic cases, without the exhibition of mercury. Since the year 1813, the correctness of the view which I then took has been fully confirmed by subsequent experiments and observations. Amongst the investigations to which I allude, those made in the hospital of the Coldstream Guards by my friend, the late Mr. Rose, of St. George's Hospital, are far the most important. The great question as to the curability of syphilis without mercury, was by him first completely settled. It was proved, that the venereal disease might be cured, not only without mercury, but without any medicines whatever. Had not the surgeons of former times been blinded by the tenets, promulgated under the influence of great names, they could have arrived at no other conclusion. In fact, many practitioners

of the 16th and 17th centuries treated the venereal disease with considerable success without mercury, that is to say, by means of guaiacum, sarsaparilla, and antimony, occasionally aided by venesection and purgatives. If it had been the character of the venereal disease always to grow progressively worse without mercury, no patient could ever have recovered prior to the epoch when that medicine began to be exhibited, which is contradicted by abundant evidence. Syphilis may be cured without mercury, not only in warm, but also in cold climates. There are many relations to prove this fact, in respect to the northern parts both of Europe and America; and many years ago, M. Cullerier, physician to the venereal hospital at Paris, was accustomed, in every course of his lectures, to demonstrate to his pupils the possibility of curing chancres without mercury, though (be it observed) he always gave that medicine afterwards for the prevention of secondary symptoms.

Mr. Rose's investigations were more successful in bringing the truth to light than those of any other person. As surgeon to one of the regiments of the Guards, he had vast opportunities of bringing the question to a decision; for he could not only put his patients under particular treatment, but he had it in his power to enforce its strict adoption, and to watch his patients for the requisite period of time. Now, he cured without mercury all the ulcers on the parts of generation, the sores of every kind, which he met with in the course of between two and three years in a regiment of soldiers, together with all the constitutional symptoms that followed them. You are not to understand, that none of those, who were cured of the primary sores without mercury, had no secondary symptoms; a certain proportion of the men, so treated, had them; but, be it noticed, that Mr. Rose cured both the primary and the secondary symptoms too on the same plan. Some of these cases were probably not truly venereal; yet others must be admitted to have been venereal, for we cannot but believe, that there must have been many cases of true syphilis in a regiment of twelve or fifteen hundred men, who were continually having intercourse with the lowest prostitutes of the metropolis. In the treatment pursued by Mr. Rose, all ideas of specific remedies were renounced; his general practice was to confine the patient in bed; various local applications were used according to circumstances; aperient medicines, antimonials, bark, diluted sulphuric acid, and occasionally sarsaparilla were administered; these were the chief means resorted to. From these and other accounts, corroborating them, there can be no doubt, that the venereal disease, both in its primary and secondary forms, may be cured without mercury; but this is not settling the question whether such practice is the right method or not? And I have only mentioned the circumstance to prove, that the old notions about the progressive nature of the venereal disease, till stopped by the imaginary specific

effects of mercury, were completely erroneous. The facts, established by Mr. Rose, are chiefly valuable on two accounts; first, as leading to more correct views of the diagnosis of the disease, inasmuch as they abolish the false doctrine, that all sores, healed without mercury, are necessarily not venereal, a maxim usually taught when I was a student; and, secondly, Mr. Rose's facts are important, as encouraging us to withhold mercury when the patient's health is not in a safe or favourable state for its exhibition. Thirty or forty years ago, surgeons were actually frightened into the use of mercury, lest the disease should get progressively worse and worse, and the mischief advance till the patient had been destroyed. For the more correct views, now entertained, the world is indebted to the surgeons of the British army; the facts, adduced by them, compel us to renounce several hypotheses which influenced the old practitioners. At all events, we must either renounce these hypotheses, or adopt the conjecture, that syphilis has absolutely changed its nature within the last forty years. But it is difficult to admit either the altered nature, or the diminished frequency of the disease; for you are to recollect, that ever since the supposed period of its origin, some surgeons have been in the habit of treating it successfully without mercury, and how is it possible to say, at the present time, that, if experiments had been made on the same great and impartial scale, fifty or a hundred years ago, the same results would not have followed; in all probability, the same light would then have been thrown upon this difficult subject, which has fallen upon it within the last few years.

Gentlemen, I have already explained to you the doctrine of Mr. Carmichael, that the venereal disease is not one but several diseases, originating from a plurality of poisons; in fact, it was Mr. Hunter's opinion, that there might be other poisons, producing effects more or less resembling those of syphilis, and such diseases he comprehended under the title of *pseudo-syphilis*, or *syphiloid* disorders. Mr. Carmichael limits the term *true syphilis* to that disease, in which the chancre, or primary sore, has a hardened edge and base, in which the cutaneous eruption is scaly, and the ulcer in the tonsils deep and excavated, seeming as if it had been dug out of the part, and, if the osseous system be involved, there are either pains in the shafts of the long bones, or true nodes. All other cases, though having many of the characters of syphilis, he does not consider as this disorder; yet, as they arise from sexual intercourse, he determines to call them *venereal diseases*. The most important point in Mr. Carmichael's theory, is, that there is a distinct and peculiar train of constitutional symptoms, arising from each particular variety of primary sore; that each variety of venereal sore leads to a peculiar and determinate series of constitutional or secondary symptoms. Now if this theory were proved to be altogether correct, it would certainly be the grandest

discovery hitherto made with regard to venereal affections. However, if we adopt the opinion, that there is a plurality of venereal poisons, we shall find, that we cannot explain many perplexing circumstances connected with this obscure disease by reference to that circumstance. I allude to instances, in which different kinds of sores are found at the same time on the same individual, or in several individuals, who have all been infected by the same woman. The symptoms of the diseases are so diversified, so capricious, so irregular, so Protean, whether primary or secondary, that the idea of a plurality of poisons will not solve many of the difficulties, which encumber the subject.

—

ANSWER TO THE CLAIMS OF WILLIAM WALLACE, M.D., OF DUBLIN, TO THE DISCOVERIES OF DR. RICORD.

BY ALRX. THOMSON, M.B., OF ST. JOHN'S CAMB.

Translator of Dr. Ricord's Papers.

—

"What faults you see in me
Pray strive to shun,
And look at home,
There's something to be done."

Old Tombstone in Stratford-upon-Avon Churchyard.

[We have let the title to our valuable correspondent's paper stand; but, upon an impartial review of Dr. Wallace's letter, we do not think ourselves authorised, by its statements or tone, to insert the introductory observations of Mr. Thomson in the language he has used in the warmth of friendship. It is sufficient, for the purposes of literary justice, to extract the following facts,—that, unfortunately, Dr. Wallace's valuable work was not known at any medical bookseller's in Paris—that a copy of it is not to be found in the Bibliothèque du Roi, or in that of the School of Medicine—and that it was totally unknown to Dr. Ricord and his friend Mr. Thomson. In fact, this able work was only published in the month of June, 1833, and this circumstance removes all doubt of literary plagiarism on either side. We know Dr. Wallace to be an upright conscientious investigator of the truth. Dr. Ricord's important papers show the extent and value of that gentleman's inquiries. So far from there being any ground of jealousy between such gentlemen, we think the coincidence of views, arising from the separate investigations of both, highly creditable to their faithful observation and talent. With these remarks we publish the medical part of our correspondent's communication.—Eps.]

Dr. Wallace says, "you are informed that my views have been promulgated, for many years, in my clinical lectures." I ask for how many years, and what are the opinions, and what the date of each? The date here is too vague for sustaining a claim to discovery. The

first regular observations with the view of their application were made in June and July, 1831, and his paper containing the results of all his researches was read to the Academy of Medicine of Paris on June 4th, 1833.

Dr. Wallace says, "that his explanation in London took place several months before Dr. Ricord commenced his experiments." Now, the time stated by Dr. Ricord is only the time at which he began to inoculate systematically, though long before this period he had observed the facts of inoculation. For many years he has been making observations of all kinds upon the various forms of venereal disease. Nor was it necessary for him, for the discovery of the fact of inoculation of the pox matter, to consult Dr. Wallace's work, since this fact is as old as Hunter; but what Dr. Ricord sets to work to investigate is, whether all forms of venereal matter produce similar effects when introduced beneath the epidermis by the aid of the lancet; and what he has clearly proved by many hundred experiments is, that no matter but that of chancre, of bubo accompanying chancre and occupying the substance of an absorbent gland, and of some cases of gonorrhoea, where there is reason to presume the existence of chancre, can produce a pustule on the skin, similar in all its characters, and susceptible of being multiplied by repeated and successive inoculations. That these inoculations may be made use of as diagnosis in cases where the chancres have lost their primitive characters, and that, to a definite period after the formation of these pustules, the same may be destroyed with nitrate of silver, so that the diagnosis may be procured without subjecting the individual to a new suffering, in passing through all the stages of this pustule. That when the prepuce cannot be drawn back, and when the vagina cannot be examined from the existence of acute inflammation, the existence of chancre may be determined by inoculation, and thus operations deemed necessary may be performed or not, according as there is danger of the wounds becoming chancreous or otherwise. That the virus of chancre can only produce gonorrhoea as an irritative, but not as a poison, inasmuch as when this is the case; the gonorrhoea so produced cannot create chancre, and does not, when inoculated, give rise to the characteristic pustule; that thence the virus of chancre is distinct from that of all other forms of venereal disease, and incapable of producing, unless irritatively, and of being produced by them.

Such are the discoveries claimed by Dr. Ricord, and such are the discoveries, with the true progress of the characteristic pustule on the skin alone, which are sustained by upwards of two hundred recorded experiments handed to the Academy, and which, for want of space only in your Journal, I have not translated; and such a series of useful results, I make bold to say, are to be found supported in no other published works, unless in that of Dr. Wallace, which we have not seen, and which even he does not venture to lay claim to, and

affects to consider them as the minor parts of Dr. Ricord's papers, and of my own appendix.

Dr. Wallace states, that "Dr. Ricord maintains, in opposition to many of his countrymen, that the venereal disease is contagious." This is not the fact; Dr. Ricord has only, as yet, published his conviction, that certain forms of venereal are contagious; and he has clearly pointed out the want of evidence with regard to others. It is true, that in this most men on the Continent were previously agreed, but Dr. Ricord has proved beyond a doubt as to chancre, not only by the cutaneous inoculation, but by successive inoculations from the cutaneous characteristic pustule. Here, then, he does not, as yet, go so far as Dr. Wallace, and consequently he cannot have copied these ideas from him.

Dr. Wallace next states, that "Dr. Ricord maintains, from his experiments, that a *characteristic pustule*, or one which follows a regular and determined course, is produced by *contact* of the venereal poison, and can be produced by no other means." Now, Dr. R. maintains the very reverse; he asserts, that the characteristic cutaneous pustule has never been produced by contact, and never under any other circumstance, except by a rupture of continuity of the epiderm, by the pulling out of a hair, a very small abrasion of the epiderm, a small leech bite, or the direct puncture of the lancet or some other cutting or tearing instrument. Hence, if Dr. Wallace asserts, as he says, that the inoculation arises from *contact*, he states the opposite of what is advanced by Dr. Ricord, and which, moreover, has not been copied by him. If *contact* be not what he means, this is but another instance of the carelessness with which he supports his invidious insinuations.

Dr. Wallace says,—"To this pustule, and the ulcer in which it terminates, I have given, for the reasons advanced, page 57, the name '*regular primary syphilis*.' How a pustule always artificially produced upon the skin, and in no way resembling in its progress the rarely seen pustular origin of *genital chancre*, perhaps on account of the difference of position and tissue, can be called *regular primary syphilis*, I am at a loss to conceive. This pustular origin of chancre has been but once or twice seen by Dr. Ricord; and one of these cases has been taken by myself, and will soon be sent to you for publication; and you will thus see how essentially different is its progress from what Dr. Ricord has called the *characteristic pustule*. Hence, as Dr. Wallace gives the same name to both, either he has not seen the progress of the latter, or he has not taken careful notes of that progress. Chancre has not the crust of the *characteristic pustule*, and the last never displays a chancreous ulcer, when the crust is not removed by artificial force or applications; for, when it falls naturally, this ulcer is always almost entirely filled with granulations, and in many cases more than half cicatrised. Such

are the marked differences between these pustules, while that of the chance of the genitals wants the areola, the most characteristic feature of the characteristic cutaneous pustule. Dr. Ricord has not even spoken of the original pustule of chancre. Hence you may judge of the care with which Dr. Wallace has studied the papers of Dr. Ricord, and the appendix by myself. Yet Dr. Wallace states,—"its history, and that of the *subsequent ulcer* as minutely traced by me, not only as they occur on the skin, but also as they appear on several other parts." How is it then that he does not mention the rupial form of crusts, and that he confounds these pustules under one and the same name.

Dr. Wallace maintains that it is his discovery that a new result of contagion may occur during the existence of the results of a previous one, without increasing the danger, or the influence upon the constitution; and he charges Dr. Ricord with plagiarism on this subject. But surely Dr. W. must be very ignorant not to know, that long before his time this fact had been admitted. If Dr. Ricord has made use of it for the foundation of his experiments, he had confirmed in his own mind, and by his experiments, the received opinion, but certainly lays no claim whatever to this opinion as originating from himself, another proof of the *careless perusal of his papers by Dr. Wallace*.

Dr. Wallace says,—"Dr. Ricord has proved by experiment that the *matter of bubo* possesses the power of producing by inoculation the characteristic pustule." Now Dr. Ricord and myself have both carefully stated that this proposition is not generally true; on the contrary, Dr. Ricord has explicitly stated, and proved by his cases, that no matter of bubo, but that furnished from the suppurating substance of an absorbent gland, consequent upon chancre, has ever produced the characteristic pustule; that suppuration round a gland does not yield inoculable matter; and hence Dr. Wallace has misquoted, or wilfully misrepresented, Dr. Ricord. And here Dr. Ricord has, without announcing it as such, made a most important discovery; namely, that during the first two or three days after such buboes are opened by bursting or incision, the matter does not produce the pustule on inoculation, while subsequently it does. The want of a knowledge of this fact by Dr. Wallace is perhaps the cause of the difference of opinion hitherto existing on this important subject, and thence the reason why, as Dr. Wallace says, "I have found this result comparatively seldom." Hence Dr. Ricord has not here copied Dr. Wallace by Dr. Wallace's own admission. But what can he mean by this phrase, which may be taken either in a good or bad sense?—"There are, however, certain circumstances which may explain these differences, and which any one who reads Dr. Ricord's paper and my work cannot fail to observe." However we take this passage, it

is negligent or malevolent, and amounts to neither more nor less than this, the constant burden of his song,—Dear readers! *read my book, READ MY BOOK, READ MY BOOK.* Dr. Ricord is not candid, is not honest, *THEREFORE READ MY BOOK*; but, whether he be so or not, still *READ MY BOOK*. Thus the littleness and weakness of MY BOOK has passed from Abernethy to Wallace! Would that with it the frank blunt generosity of the former had transmigrated at the same time into the latter!

Dr. Wallace says, “on three occasions Dr. Ricord produced the characteristic pustule, by the inoculation of matter of blennorrhagia, or in my language, of catarrhal or gonorrhoeal primary syphilis, taken from the urethra of males, in whom *there was not the least external excoriation, or any visible ulcer of the urethra.*” It is, however, to be observed, that the conclusions which Dr. Ricord has drawn from these experiments, are not the same as those deduced by me. Indeed, his conclusions are not quite clear. Such is the passage that Dr. Wallace dares bring forward as the result of what Dr. Ricord thinks true, and of what I have maintained. Dr. Ricord has more than three times produced the pustule from urethral gonorrhoeal matter, both in men and women, and I have distinctly stated, that although in these cases no external excoriation or ulcer could be found, and in the female no vulvar, vaginitic, or uterine chancre could be found, yet in two or three of these an actual chancre was found in the urethra, not far from the orifice of the external meatus urinarius; and I have moreover, with Dr. Ricord, stated, that in no case in which gonorrhoeal matter coming from those parts capable of being examined, as the vulva, vagina, or os tincæ, or the space between the prepuce and gland, although previously to the inoculation, these parts, from the accidents of irritation or inflammation, or their consequences, could not be examined, have chancres failed of being found, when these parts have been subsequently examined; and from these two circumstances combined, Dr. Ricord has drawn the inference, that gonorrhœa is incapable alone of producing the characteristic pustule. I leave it to the public to judge, whether these statements are wanting in clearness and precision, and I leave it to them also to say, whether this be *hypothesis*, or pure deduction, deduction, indeed, of high analogical probability, yet deduction of which Dr. Wallace, after these statements, has the hardihood to say, that Dr. Ricord or myself admit, “*there was not a shadow of a proof.*” If this be a specimen of the candid criticism and of the logic of Dr. W., surely his work must be a very curiosity, a very type for those who wish to leave medicine in the most perfect obscurity. Besides, here he again makes us state things not to be found in our papers, and adds to the proof of his negligence and of the quixotic nature of his literary combats.

Again, another misconception or perversion

of Dr. Ricord's statements. Dr. Wallace states, “Dr. Ricord, if I understand him right, maintains from his experiments, that the matter of the *characteristic pustule* will produce in certain habits the serpiginous ulcer;” and Dr. Wallace acknowledges to have advanced such a very doubtful opinion in his work. In this, then, he again erroneously accuses the plagiarism of Dr. Ricord, who states the very reverse. He states, that in two cases the matter of serpiginous ulcer, resulting from suppurated bubo, the consequences of chancre, gave rise to the characteristic cutaneous pustules, and that these pustules, after having for some time followed the ordinary course, took on themselves the serpiginous form, and inquires whether there be not something in the constitution tending to modify the chancre into the serpiginous form? The diametrical contrasts between these statements, and those lent to Dr. Ricord by the quixotic spirit of Dr. Wallace, are too manifest to need further comparison, but not too manifest to stamp the want of candour on Dr. Wallace's criticism, the continued effort to bring himself into notoriety even at the expense of truth.

Again, Dr. Wallace states, that “Dr. Ricord admits, as a consequence of blennorrhagia, alterations of the bony and mucous system, and pustules on the surface of the skin.” Now no such statement is advanced in the writings of Dr. Ricord, who has never advanced that blennorrhagia, unaccompanied by chancre, is followed by alterations of the bone. Of the mucous system, indeed, he admits alterations, and states these at much length, and with uncommon care, and in a manner which no other man could do, from the nature and original mode of application of his speculum, a discovery, or rather an original application, under all circumstances, which is of the highest importance, and which even the extensive claims of the accurate Dr. Wallace cannot embrace. But as to pustules upon the skin, no such thing is stated, the expression is *mucous pustules*, which is the French name for *mucous papule*, and which I have explained to mean in my translation, *papule*, oozing a peculiar matter. This very mistake appears to me to be a proof of Dr. Wallace being as ignorant of the French authors and their synonymes, as he has been careless and negligent in his perusal of Dr. Ricord's papers.

Again, Dr. Wallace says, “It is the conclusion of Dr. Ricord that there exist no symptoms by which virulent blennorrhagia can be distinguished from certain non-virulent discharges.” How different this from the following statement of Dr. Ricord, which I give in his own words “*Enfin privé incontestablement de ce caractère (la possibilité de produire des chancres inoculables) il n'est qu'une espèce de blennorrhagie virulente; c'est celle qui, bien observée pendant tout son cours, et n'étant pas compliquée, ce dont on peut mieux s'assurer chez les femmes par la facilité avec*

laquelle les organes sont vus dans presque tout leur étendue, est cependant suivie de symptômes consecutifs, tels que les papules muqueuses, &c., et alors la présence de ces symptômes est le seul caractère qui puisse rendre le diagnostic précis." Such are the words of Dr. Ricord; I leave it to all the world to judge of the foundation, as of the accuracy of the criticism. Dr. Wallace now says, that, "on the other hand, it is maintained, at least by the translator of Dr. Ricord's paper, that a diagnosis of the characteristic pustule may be obtained from a consideration of all its phenomena." Such words are not to be found in my notes, in which I have simply described facts, although the conclusion is fair from the facts given; and without reference to the fact of chancre being produced directly without any preceding pustule, when chancrous pus is applied to an abraded or denuded surface, it was stated to complete the result of our observations, without at all being claimed as a discovery, for it is a fact known long before Dr. Wallace's time. We willingly yield the honour of so important a discovery, as that where there is no epiderm, there can be no pustules, to the abused Dr. Wallace.

And Dr. Wallace states, "The following opinions, which will be found embodied in the views respecting ulceration, &c., given from p. 49 to p. 55 of my work, viz. that the contagious quality of the '*characteristic pustule*,' may persist after the healing process has commenced, and even until the ulcer is perfectly healed; that the formation of bubo requires certain relations between the surface of the '*characteristic pustule*,' and the absorbent orifices; and that no contamination results from the '*characteristic pustule*' in its primitive state."

Here are three misquotations. In the first the observation applies only to the characteristic pustule on the skin, and not, as Dr. Wallace presumes, to that on the genitals also, although both have been determined, independently of that gentleman's researches. In the second Dr. Ricord states the very opposite of the proposition, namely that bubo, inoculable bubo, results when certain relations exist between the chancre and the absorbent orifices, and not between the characteristic pustule and the absorbent orifices. And such is the accuracy of Dr. Wallace that he has not remarked that I have distinctly stated that I have never seen suppurating bubo as the consequence of the *characteristic cutaneous pustule*, although there generally occurs more or less swelling, induration, and tenderness of the corresponding absorbent glands. For the third, I confess I am at a loss to know what Dr. Wallace means by the word *contamination*. It is a word attributed to myself, and not to be found in my appendix, and certainly not in Dr. Ricord's papers. What we have both stated is, that in no case, in which inoculation has been practised, have the patients as yet returned to the hospital with secondary symptoms, or have

had such symptoms developed during the existence of the pustules, or their consequences. Further than the fact goes we presume nothing; but Dr. Wallace says we have copied the word *contamination* from him. I can assure him he will find it difficult to trace in our papers any such unscientific and unmeaning terms. Dr. Wallace again says, "it is communicated that if the nitrate of silver be properly applied during any of the four first days of the progress of the '*characteristic pustule*,' it will be arrested in its course and healed; a position particularly enforced by me from page 92 to page 99 inclusive." Now this remark of Dr. Ricord's applies only to the cutaneous pustule, he having never robbed the Italians of their success with this method for the genital chancre, and constantly attributed to its authors; and his object in ascertaining this fact was only to try to destroy by some means the inoculatory pustule, as soon as it had served for diagnosing the original ulcer, so that the patient might not have the trouble of having two sores longer than necessary, this diagnosis being hitherto requisite, when the original ulcer has lost its primary characters. How then could this be robbed from Dr. Wallace?

Our opponent finally charges Dr. Ricord with having fallen into errors, but he does not name them. All are liable to err, even with the best intentions, and it is indeed unkind in Dr. Wallace, and somewhat inhuman, to leave Dr. Ricord in error until his new volume shall be completed. What! to give a little more eclat to my work, errors recognised by him publicly are not to be pointed out, and the patients, the numerous patients, some hundreds a week, of Dr. Ricord, are to be allowed to be sacrificed to the Doctor's negligence or error, because, forsooth, the new volume is not ready. O, fie! Humanity is of more importance than originality of discovery, and assuredly more productive of true and lasting renown. Such are the flimsy assertions of Dr. Wallace, such are the phantoms brought forth by his inaccuracy and negligence, or wilful want of comprehension, and from such things as these,—such Quixotic shadows, has been raised a serious charge, invidiously brought forth, and unfairly, uncandidly, and unmanfully exposed. I trust that ere Dr. Wallace again enters the lists he will polish his weapon and raise his visor, lest, blinded by his self-importance, he again charge the starting post, instead of the enemy against whom he would plant his lance. His accusations I retort with indignation and disgust, and I conclude with his own phrase, "render to Caesar the things that are Caesar's, and to God the things that are God's."

As soon as Dr. Ricord can procure his book be sure that it shall be fairly and candidly examined, and that his phrases shall neither be mutilated nor tortured.

[We shall insert the continuation of Dr. Ricord's paper on blennorrhagia in women, at our earliest convenience.—Eds.]

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833-34.

LECTURE I.

GENTLEMEN,—You may have often heard that the approaches to science are rugged and uninteresting, and some of you have perhaps experienced the truth of the remark. Hence the custom of delivering an introductory lecture, in order to lay before the young mind, when first entering on each path of knowledge, the objects, the results, the attained good, and the hoped-for glory of the pursuit. These are to be displayed with clearness and with truth, yet it is obvious, that much of the effect of such a lecture must depend on the nature of the subject, and the judgment of the speaker; and it is well when the exalted nature of the one is attainable by the capabilities of the other. Such a lecture, then, should be an earnest lesson on the objects, the pleasures, and the advantages of that science, of which the course is destined to treat; its history, its true mode of study, its interests, actual state, and future prospects may all form legitimate subjects, and when thus rightly viewed, an introductory lecture, so far from being a mere ornamental appendage, may become a most important part of the course.

With these views let us approach our subject, the theory and practice of medicine. Let us contemplate that study and that profession, which, venerable by all antiquity, yet in itself is "ever new." Even in its infancy, when the world was in darkness, was medicine a glorious science when compared with its contemporaries, and its first professors were ennobled and exalted by its influence. As their mantles descended through a long line of illustrious successors, we see medicine progressively expanding, and even when the night of barbarism hung gloomily over the earth, we see its genius triumphing over the surrounding darkness, and shining in the east as a beacon to the shipwrecked mind of man; and I trust that I shall be able to prove to you, that, in our own time, when the human mind has made such astonishing advances, that medicine has kept pace with her sister sciences, and it is a gratifying reflection to think, that among the most distinguished promoters of the collateral sciences, physicians have ever held a commanding rank, thus proving themselves foremost in knowledge, as they have ever been in philanthropy, in private and public charity, and in all good will to man.

It is scarcely necessary to allude to the title of this course of lectures, further than to remark, that however different they may be in name, it is yet impossible to draw the line of distinction between the theory and the prac-

tice of medicine. If medicine were merely the knowledge of a number of empirical remedies for particular symptoms, given without our enquiring into their mode of action, or any acquaintance with the dependence of one function, or one viscus, on another, of any knowledge in short of physiology in the healthy or diseased state, then we might have a practice of medicine independent of what is called its theory. But medicine now holds a higher place, and much of its improvement is traceable to our advances in physiological and pathological science. Thus to treat, or teach, the treatment of a disease, we must know the healthy function of the organ, or organs, the history of development, the influence of other organic systems, the changes produced by disease, and, as far as possible, the action of all external or internal agents on the viscera. But this is the theory of medicine.

For example, let us suppose that we are called either to treat or to teach the treatment of a case of enlarged liver. Let me here remark, that in selecting this case I do not wish you to suppose that I am one of what might be called the hepatic school of medicine, in which the existence of almost every organ, except the liver, seems to be forgotten, and of which the creed seems to be, that there is but one viscus, the liver, one source of disease, biliary derangement, and one cure, mercury; a creed which, though not enforced and defended by the sword, has lost perhaps as much of human life as others, whose history is written in letters of blood. But no one can doubt the importance of the organ, and I have taken it to illustrate the connexion between the theory and the practice of medicine.

You detect an enlarged liver; you are called to cure the disease:—

1st. You must be aware of the healthy state of the organ, and of its healthy functions, as shown by the volume, sensibility, influence on digestion, and the healthy state of the secretion. You must know all these, as it is by the departure from these conditions that you recognise this disease at all.—*But this is the theory of medicine.*

2ndly. You must know the history of its development, because there is a period of life when the natural state of the liver is in a greatly enlarged condition, and this may continue even to adult life, and produce an enlarged liver, not the result of disease but the arrest of development, and the question will arise as to whether the case before you is an example of this, or of recent and actual disease. The whole treatment turns on this.—*Yet this is the theory of medicine.*

3rdly. You must know the influence of other organic systems. An enlarged liver may be produced mechanically by obstructions in the lungs or in the heart; it may be produced from the sympathetic irritation of a duodenitis, or be the result of original disease in its own structure. All these circumstances must be known and taken into account. If it be

merely obstruction in the venæ cavæ hepaticæ the ordinary treatment will not answer; if there be duodenitis we must modify our treatment, and so on. We must know these things; we must know how to recognise these diseases before we can prescribe or practise successfully. All this is that part of the theory of medicine called pathology, or the physiology of the diseased body.

4thly. You must know the effects of disease on the liver itself. Some of these are removable by art, others are totally incurable. You must know these in order to determine on the probability of their existence.

5thly and lastly. You must know the influence of remedial agents on the liver and the adjacent organs. You must be familiar with the effects of stimulation of the mucous surfaces of the stomach and duodenum. Then, indeed, and not till then, will you be qualified to treat the case with judgment and success. The same remarks, I need scarcely add, will be found applicable to the diseases of each viscus in the body.

The objects of medicine, gentlemen, are twofold; first, to cure disease, no matter where seated or how produced; and secondly, to relieve bodily suffering in cases where a cure is impossible. Its great end is to prolong life, and to diminish the bodily evils which result from the infirmities of our nature and other circumstances. Some of you may ask, where then is the distinction between medicine and surgery? In truth, there is no distinction in reality, and there should be none in theory. The human constitution is one;—there is no division of it into a medical and surgical domain; the same laws and the same principles of treatment apply to the cure of a fractured bone and the cicatrization of an internal ulcer. Unlike the corporations of medicine and surgery, the supposed purely medical and purely surgical parts of the body live in excellent harmony. Here, then, there is no division, no jealousy, no separation of interests.

I am by no means prepared to deny that advantages may arise from a practitioner devoting himself to this or that branch of his profession; but, if he seeks for eminence, he will first educate himself generally. Let him attain extended views of pathological medicine; let him make himself master of the actual state of the science, and then he will find that there is not a single fact or law with which he has become acquainted that will not have its bearing on his particular pursuit. It is in the education of medical men that the ruinous effects of the division of the professions of medicine and surgery are most perceived; and I feel convinced that, of the two, *the surgical student is the greater sufferer*, because his views of pathology are injured. All the great laws in pathology are drawn from the consideration of visceral disease; yet the attention of the surgical student is diverted from this, and directed to what, I will say, can never elevate him in the ranks of science.

He is taught anatomy, and what is called surgical disease, but he is kept ignorant, by this wretched system, of the greater part of his profession, until he comes to practise, when, if he has a mind fitted for observation, he will find, that for one dislocation there will be hundreds of visceral diseases; and he will discover what was concealed from him during his pupilage, *that many, many more die of what are called medical than surgical diseases*. During the late war, more men in the British navy died of fever than of all other causes—including the sword. But, I rejoice to say, that in Dublin the exclusive system of education is fast wearing away, and one of the many excellencies of our national school of medicine is the instruction in general pathology. There are few schools of medicine where now a more enlarged and liberal spirit of education exists.

In the study of your profession, gentlemen, let me warn you not to allow yourselves to be misled by the idea that surgery and medicine are different in their nature. The mere surgeon or the mere physician only knows half of his profession. Reckless of human life, he may practise the healing art as a trade, but he never can know it as a science. But, as there are infinitely more cases of what are termed medical than surgical disease, it is plain, that the surgeon, ignorant of medicine, will far exceed the physician ignorant of surgery, in the extent of his malpractice. I have long observed the ruinous system which has been pursued by teachers, as connected with this subject. The pupil was taught to consider, that if he was a skilful anatomist, if he understood the routine surgery of an hospital, and had carefully studied certain works on surgery, and some obsolete books of pathology, he was thereby prepared, in the language of the schools, to go forth to teach and practise the art and mystery of medicine in general. Now, all this was wrong. You may be profound anatomists and be bad surgeons, and worse physicians; you may have by heart the writings of Pott and Desault, of Hunter and Thomson, and be totally incapable of treating a simple or complicated fever, or a case of visceral disease. But it is not necessary to say more. Society demands that the old system of a division in education should be abolished; and ere long, I even trust to see a fusion of the profession, when much of the present evils must cease, when medical men shall have a common centre, from which they will receive a common impulse; when their efforts shall be solely directed to the increase of medical science, and the political and moral exaltation of their profession; and last, yet not least; when the ingenuous pupil shall not be led astray; when he shall not be told by one teacher to despise this, and by another to neglect that part of his profession; but having the *whole* of the noble science of medicine thrown open to him, his mind, unwarping by prejudice, unfettered by fear, shall be permitted to take that right view of his pursuit,

that alone can lead him, and assuredly will lead him, to the honours and successes which truth bestows on all its votaries.

I have said, that the exclusive system of education had singularly diminished in Dublin. Indeed, our national school has earned great reputation for general pathology; and from a long and cordial intercourse with the class of Dublin, I will affirm, that there are few places where we can see such zeal, talent, and thirst for knowledge among the students. As an Irishman, addressing my own countrymen, let me congratulate you on the fame the Dublin School of Medicine and Surgery has now acquired, and is every day acquiring; and when the strength of Irish talent, aided by the proper working of our unrivalled institutions, is brought into play, may we not anticipate a still more glorious result? This reflection has often cheered me, that within the last few years there has been a greater stimulus infused into the science and literature of this country. Amid the ungenial influences of political excitement, and the animosities of party, how gladly should we contemplate the advance of what will prove an honour to our national character, and an advantage to mankind. It is like the growth of the coral into rocks and fertile islands, though surrounded by the strife and waste of waters. Our scientific societies have multiplied; our periodical literature, the want of which furnished so fruitful a theme for cavil, has been extended so as to afford a wholesome and vigorous supply in the varied departments of literature and science; and our monthly and quarterly publications are taking their proper place among the ranks of British journals. When we turn to works of a more permanent kind, we also see cause for satisfaction. Many most important works in anatomy, surgical pathology, physiological medicine, and midwifery, have lately issued from the Irish press; and the Irish contributions to the *Cyclopædia of Practical Medicine*, are allowed on all hands to give to that work no mean portion of its value.

There are few more wholesome exercises for the mind, few so necessary and so useful as the comparison of the actual state of any science with its advance and character at a former period; and it is in this, most chiefly, that the value of what is called the history of medicine consists. We study it then, not as a matter of antiquarian research, of learned curiosity, but as the picture of the human mind, now on the right path, now misled by error, yet still struggling onward; as the record of a dear-bought experience, and a beacon to warn us of the rocks and shoals that beset its future progress unto truth. To analyse the actual state of medical science, to show you all that has been done within a little time, to display all old pretensions to the character of a true and thrice noble science, would far exhaust my capabilities and your patience. Let it suffice to contemplate the improvement con-

sidered generally, and the means by which that improvement has been attained.

It is an error too generally received that medicine owes all its advances to the researches of modern times. Far be it from me to undervalue these, but I believe that the opinion I have alluded to is wrong, and is perhaps kept alive by our own vanity; for by a specious deception we often take to ourselves the honours and distinctions of the time we live in. The truth is, that medicine, like many other of the sister sciences, has been long steadily advancing, and the flippant every day remarks that the *inductive system* (that is the observation of facts and the embodying of those conclusions that legitimately flow from them) has been only introduced into medicine in our time; and that our predecessors in medicine put theory first and fact second in their medical philosophy, are "*as false as dicers' oaths*." Have the authors and teachers who are so fond of decrying the medicine of a former day at a time when they are (perhaps innocently) making use of its facts and observations—have they read the writings of the father of medicine? Have they studied that "*aureum opus*," so well called from its lustre, its purity, and surpassing value? Was Avicenna a mere theorist? Did Morgagni observe no facts, nor truly record them, even at the expense of his medical reputation? Is there no induction in Baglivi? Was Haller unacquainted with the method of experiment and induction? Or is the discoverer of the circulation of the blood, the good, the great, the injured, but the immortal Harvey, forgotten? Where do they place Boerhaave? and shall the name of Sydenham go down with his ashes to oblivion?

The true state of the case is, that medicine, in its present advanced state, only represents the improvement in other branches of human knowledge, all of which are so intimately linked together, that although their extremes be far removed, there is a point where all are reciprocally cause and effect; so that if we take any one of them, it is easy to show its intimate bearings with, and importance to, all the rest. We have been long advancing in medicine, and though I admit most fully the vast strides which have been made, still I must here declare my firm conviction, that the study of the older authors is too much neglected, and that in them you will find a treasury of knowledge, much of which you may think to be the production of modern times.

If the writings of the ancient authors only contained a small portion of the information with which they abound, it would be a sufficient stimulus to their study; to reflect that it is in them, in the medical writings of the ancients, that the germs of the inductive philosophy are first to be found. It is then in the old regions of medicine that we find the fountains of that mighty river, which for 2000 years has fertilised the earth, and made man its lord. Had the progress of man not been retarded by

the ignorance which is the child and servant of barbaric despotism, an earlier Newton might have enlightened the earth, an earlier Laplace have measured the heavens, or a Cuvier declared the glories of a past and present creation. The mind of man would have burst its chains, and ages ago have formed that holy alliance with knowledge and her first-born, liberty, which now is its safeguard and its glory. I repeat it, in the writings of Hippocrates you will find the principles of the inductive philosophy. A physician showed Bacon the road to immortality.

We find that there is in the mind of man a tendency to reverse the true mode of reasoning, and to seek for a principle before it has observed facts, and this was the cause of the retardation of medicine, as well as of all other sciences. Hence the various schools from Pythagoras to Cullen or Brown in our day. But a slow though sure revolution was long going forward, and I believe that Cullen and Brown were even *behind* the actual state of medicine in their time. Physicians turned disgusted from the war of words and doubt to seek in tangible objects the certainty which these only can produce; in a word they began to follow the Baconian system more generally. They reverted to the instructions of Hippocrates, and from that period our modern improvement may date. They turned their attention to the examination of those changes which disease produces on the human body, and connected these with the symptoms observed during life. And what has been the result of this?

1st. The accumulation of an enormous number of facts, relative to the changes of organs produced by disease.

2nd. The connection of a vast number of these changes with particular symptoms, and hence the advance in diagnosis.

3rd. The establishment of the true value of symptomatology, and the verification of that all-important fact, that opposite states and organs may produce similar symptoms.

4th. The knowledge of the vast class of latent diseases; in other words, diseases which exist without influencing the phenomena of animal life, or, in some cases, the phenomena of both animal and organic life. Diseases either without symptoms at all, or only with such as previously were not supposed capable of leading to their detection. You know that the phenomena of life are divided into two classes, viz. those of organic or vegetable life, such as *nutrition, circulation, absorption, respiration, secretion*. While those of animal life, or the life of relation (so called from its being the source of our connection with surrounding bodies), are the senses, the phenomena of mind, and muscular motion. The one life seems more under the influence of the ganglionic, and the other under that of the cerebro-spinal system of nerves.

As some of the junior part of the class may not have accurate ideas as to the meaning of

symptoms, I may state that disease is recognised by signs and symptoms.

By signs we mean those mechanical alterations, produced by disease, in the conditions of parts, which are recognisable to the external senses of *touch, sight, and hearing*; *changes in appearance, volume, shape, resistance, peculiarities of feel*, and the production of *sounds*. We may make a diagnosis by signs alone. Take for example a case of tympanitis. The abdomen is prominent, enlarged, circular, elastic, and sounding like a drum when struck. Thus we learn that the belly is distended by air.

Now, *symptoms* are totally different; they consist in certain changes produced in *functions*; and these functional changes are to be considered in a threefold manner:—

1st. Changes in the functions of the part itself.

2nd. Changes in the phenomena of organic life.

3rd. Changes in the phenomena of animal life.

Let us take, for example, a case of inflammation of the stomach. We have, first, changes in its own function,—morbid sensibility, vomiting, thirst, anorexia. In the next place, we have changes in the functions of organic life,—fever, from the action on the circulating system; hurried respiration, and cough, and hiccup, from the action on the respiratory system; jaundice, from its action on the biliary system; suppression of the secretion of the skin, kidneys, &c. All these, you observe, are lesions of the functions of organic life.

But we may have other symptoms; prostration, headach, delirium, convulsions; these are lesions of the life of relation, or animal life.

Now, in many cases, we have to combine these sources of knowledge to form a correct diagnosis. Take, for example, a case of hepatitis.

The patient has had pains in the hepatic region, fever, jaundice, hurried breathing, tenderness. After some time he has a tumour; the side dilated; the hypochondrium dull on percussion. Well, the signs point out an enlargement of the liver; the symptoms, that the cause of that enlargement was an acute hepatitis.

In general we may state, that signs only declare the actually existing mechanical condition, while symptoms, either present or past, point out the cause of the change, whatever it may be. Both must be studied together; but you will learn more from symptoms without signs, than from signs without symptoms. But to return to the results of the improved method of investigation.

Great light was thrown on fever in general; and it is, I believe, quite true, that all the advances which we have made in the knowledge of fever, are due to the prosecution of pathological anatomy. Almost all of what we may call our general knowledge of fever is

due to Hippocrates; but anatomy has revealed its effects, its complications; and the all-important fact, that the cause of its fatality is often local inflammation. This knowledge, however, is not so new as is taught by some modern systematists. Galen (*De Affect. Intern. c. xli.*) taught that in continual fevers bleeding and cold drinks were the powerful remedies. Sydenham declares that the ignorance of the inflammations in malignant fevers, has been more fatal to the human race than the invention of gunpowder. Baglivi, that malignant fevers often depend on a visceral inflammation, and Van Swieten knew the frequency of intestinal ulcerations in typhus.

Among the direct results of pathological anatomy, it is shown, that *disease is seldom confined to one organ, or even one system*, and thus it has utterly shaken the nosological system of Cullen and his predecessors, which you know consisted in classifying disease by symptoms, which were supposed to point out a certain and single disease. For example, the nosologists class *phthisis* as an affection of the lung, but pathological anatomy has shown, that in many cases it is the result of a disease invading many organs and systems, and that the pulmonary disease is but a link in the chain of morbid actions. Pathological anatomy also has demonstrated the inflammatory nature of a vast number of diseases, and has thus given us a key to treatment, to prevention, and to palliation when the disease is incurable.

The last grand result of pathological anatomy, is the discovery that a vast number of affections, supposed to be merely lesions of function, are more or less connected also with alteration of structure. Thus many of the dyspepsias of the nosologists are proved to be examples of gastritis, or of other organic diseases; cases of asthma turn out to be chronic inflammation with emphysema; the palpitations may depend on organic disease which has sprung from a carditis, and so on. I need not now dilate on the vast importance of such facts to practical medicine.

But let us now come to an all-important inquiry. Is pathological anatomy to be considered as the basis of medicine? or is it, even when combined with clinical observation, the foundation of all medical knowledge? This inquiry, you will at once perceive, involves the question as to whether Hippocrates and his followers have done anything for the science, or whether medicine is wholly new, an infant, and consequently a weak and imperfect, science. Are we to despise the works of the ancients, to be ignorant of them, and to allow medicine to be in its infancy. In fact, if we review the history of medicine from the Hippocratic era to the absurdities of Hahnemann, we find that there have been two orders of men, one constituting what we may term the school founders, who made a theory, and sought to square facts to meet that theory; these have

only brought disgrace on medicine. The other class consists of the Hippocratic observers, that is, of men who sought for facts, who collected and pondered on these facts, in other words, who were Baconian philosophers. It is the labour of these that has really advanced medicine. Asclepiades, who lived in the first century of the Christian era, declared that the medicine of Hippocrates was a *cold meditation* of death. The celebrated Thessalus, who lived under Nero, in writing to the emperor makes use of the following words:—

“I have founded a new sect, which is the only new one. I have been forced to this, because none of the physicians who have preceded me have discovered *anything useful*, either for the preservation of health or for the cure of diseases, and because Hippocrates himself has put forward many dangerous maxims.”

And what was this new doctrine? That nature in each case pointed out to the patient what was most fit for him, and that hence he should be diligently supplied with every thing that he fancied.

We have next Paracelsus. He commenced his course of lectures at Basle, in the year 1526, by publicly burning the writings of Galen and Avicenna, and assured his auditors that a single hair of his head contained more knowledge than Hippocrates and his successors. He taught the cabalistic medicine, the intimate connexion between the planets and the viscera; he was a vitalist, but embodied his vitalism under the shape of a demon, who resided within the system, and which he called *Archæus*. Diagnosis was to repose on the examinations of the stars, and not on symptoms. He invented the doctrine of tartar, which is the cause of all diseases, of accumulation, obstruction, and concretion; “and I call it tartar,” says he, “because it contains the oil, the spirit, and the salt, which burn the patient as hell does.”

Hahnemann, the founder of the homœopathic doctrine, may be quoted next as an example of these school founders, and he, like his predecessors, expresses himself with all that arrogance, which ignorance, when it pretends to learning, invariably assumes. Speaking of the Hippocratic medicine, he says,

“*Since this art only consists in a gross imitation of a dangerous and insufficient process, it must be admitted, that the true medicine was not discovered until by me. It is the infallible oracle of the art of curing; it is the sole mode of really curing disease, because it reposes on an eternal and infallible law of nature.*”

And what is this mode and doctrine?—We have it in four propositions, and it is hard to say which of them is most revolting to common sense. We are told that it is absurd to seek for the cause of symptoms in order to remove them;—that we must cure diseases by the exhibition of substances which would otherwise produce them; that the dose is to be inconceivably small; and that there are

three original diseases from which spring all the maladies which afflict mankind,—syphilis, syccosis, and the itch! These are the fruitful causes of all diseases, epidemic, sporadic, idiopathic, and symptomatic. Like his predecessor in quackery and deceit, he, too, has in his syphilis, syccosis, and itch, the oil, the spirit, and the salt, which burn the patient as hell does. Like Paracelsus, too, he maintains the curability of diseases, and is a disciple of the animal magnetism.

Let us next see how Broussais announced his doctrine to an admiring world.

“After so many vacillations in its march, medicine at length follows the only path which can conduct it to truth—the observation of the relations of man, with external modifications and the relations of the organs of man, one to the other.” This is the physiological method, because it cannot be followed without studying life.

I am more anxious to draw your attention to this doctrine, as Broussais may be considered as the source of the anatomical school, which of late was so completely the fashion, —if I may use such a term; and it is a striking instance of the danger that attends the idea of our having made a discovery, to see a man like Broussais, than whom few have really added so much to medicine, falling into the same fault of arrogance and contempt towards his predecessors.

At this moment the medical world, particularly on the Continent, are divided into two great sects. One may be called that of the *pathologico-anatomists*, the other the *Hippocratists*. The first declares that diseases are *primatively local* in all cases; that the symptoms—say in a case of fever—are only the *results of a sympathetic irritation from some local disease*, which is to be *attacked with vigour*; that pathological anatomy is to be the foundation of all practice; that there is nothing approaching to a *specific in medicine*; and that *Nature makes little or no attempt to cure*. Their favourite maxim is that saying of Bichat's,—“*What is observation if we are ignorant of the seat of disease?*”

This is the sentiment of an anatomist, but not of a physician; and we must regret that it once escaped the author of the “*Researches on Life and Death*,” a book of such interest and such beauty, as to captivate even the non-medical reader, and make the very name of Bichat be hallowed in our memory. Many are the diseases of which we know not the seat; yet in which observation, Hippocratic observation, is of the greatest utility.

We know not the seat of fever, let the followers of Broussais say what they may to the contrary;—yet is observation of symptoms of no avail in fever? Are the effects of contagion, the history and nature of epidemics, the termination by crisis, the results of treatment, of symptoms as connected with prognosis, — is the observation of these useless or

unnecessary? Sydenham knew not the seat of variola; yet he declared the true principles of its treatment. There are very many diseases on which pathological anatomy throws but a negative light,—if I may use such a term,—particularly affections of the fluids, and the neuroses.

So much for the doctrine of the anatomical school. I beg of you not to misunderstand me as undervaluing pathological anatomy; I only wish to show you its true value. I believe there could hardly be adduced a single fact in pathological anatomy that has not its distinct bearing on practical medicine. And it is true that the diseases whose treatment is best understood, are those whose pathological nature is best known. Even in fever, the actual nature of which has not been revealed, great advantage has been derived from anatomical researches; for all the advance in our knowledge of this Protean disease consists in ascertaining the number, nature, and seat of the local inflammations which accompany or arise in the course, and complicate the disease.

Let us, lastly, revert to the opinion of the Hippocratists.—They admit that *vast advantage* has arisen from pathological anatomy; but they see that its light is limited within certain bounds. They believe that great advantage is to be derived from the careful study of symptoms, even in cases whose pathological nature is not revealed by the knife. They believe that there are many diseases whose local origin cannot be demonstrated; for instance, *fever*. They deny that pathological anatomy is always to be our guide; but admit a rational empiricism, and the use of remedies which may be called specifics; and, lastly, they hold that nature in many cases makes an attempt to cure; and that the physician, in the words of Hippocrates, is to be *the minister and interpreter of Nature*, rather than her master.

Let us then combine the precepts of the founder of medicine with the lights of modern science. Let us take *observation*, and that observation rendered fruitful by study, for our guide; and let the observation equally embrace the phenomena of the living as well as the dead. Let us be Hippocratists in the dissecting room as well as at the bed-side. By comparing the practice of these two schools we get more accurate ideas as to their doctrine. The anatomists, holding that all diseases are local, direct their whole attention to the discovery of the lesion and its connexion with symptoms. This, with their doctrine that almost all diseases are inflammatory, leads them to a strict general and local antiphlogistic treatment. Fever is to them symptomatic, and the supposed source is to be vigorously attacked in the commencement. *Diathesis, the nature of the epidemic, and the powers of nature*, to effect a cure, are comparatively neglected. They inhibit purgatives for fear of increasing the local inflam-

mation, and lose many patients for want of a timely support of the powers of life.

They deny specificism in disease as well as in medicine, and are sorely puzzled to explain the extraordinary powers of bark, and mercury, and sulphur, and iodine. They despise the experience of the past.

The true Hippocratist, on the other hand, believing that we have not yet arrived at the knowledge of the local origin of all diseases, and particularly fevers, grounds his practice accordingly. He draws his experience from the recorded knowledge of the past, and his own unbiassed observation. When he recognises a local inflammation he meets it with judgment, taking into account the habit, diathesis, epidemic, constitution, and tendency to crisis. He trusts much to nature, and watches her operations, particularly in fever. He is not afraid of moderate evacuations; the phantom of a local inflammation does not always haunt him; and even where he recognises its existence, that does not prevent him from using a stimulating and supporting treatment, if the general state of the patient requires it. He treats particular diseases by particular remedies, the utility of which has been proved by experience—such as syphilis, scrofula, intermittent fever, and so on. He uses the expectant medicine, which is not inactive treatment, but founded on the observations of the powers of nature:—“*Natura morborum medicatrix*,” but he never loses the opportunity of doing good when such presents itself, remembering the first aphorism of his great master:

“*Occasio præceps.*”

I have great hopes for medicine, for I see men's minds turning to the true path; and I trust that all whom I now address will deem themselves as labourers in the great work. Think what a noble science you profess!—the only one relating to earth-born things, which, while it ennobles the mind of man, yet softens and expands his heart; whose source is all science, whose end is good to man. Above all things follow truth; Nature can never deceive,—see that you be her faithful interpreter. The great evil is, that there has as yet been adopted no means by which the experience of the past can be brought fully to bear on the actual teaching and practice of medicine. Too often has the physician to create his own instruments. But when all the scattered facts of medicine are collected, whether they be the observations on the living or the dead body, as old as history or as young as to-day; when these votive tablets are hung up in the temple of truth, and their facts verified, compared, and classified, then, and not till then, will you see medicine in all her glory.

French Medicine.

Of the Frequency of the Pulse in Insane Persons, considered in respect to seasons, atmospheric temperature, changes of the moon, age, &c., with a refutation of the received opinion concerning the decrease of the frequency of pulse in old men.

TRANSLATED FROM THE FRENCH OF MM. LEURET AND METIVIE.

It has for a long time been our desire to know the frequency of the pulse in insane persons, and the laws to which this frequency is subject. To obtain this end, it was absolutely necessary that our observations should be made on a great number of individuals; that they should be tried as well upon males as upon females; and, finally, that, during our observations, we should carefully note all circumstances, both physical and moral, which might exercise any influence over the pulse. We have complied with these conditions, one only excepted. The assiduity, which an undertaking of this kind required, has prevented us from examining the pulse of the male in so complete a manner as that of the female. Our proximity to la Salpêtrière, and the advantage that one of us had of being charged with the treatment of a part of the insane females received into that hospital, rendered the examination of the pulse of these females easy. We have likewise made observations on the insane persons, both male and female, under our care at the Maison de Santé d'Ivry, but the number of patients received into this house being small the observations we have made upon the males are not sufficient to draw any particular conclusion. Our observations, therefore, refer principally to females.

It will be seen in the report of our experiments, that we took every precaution to ensure results as near to truth as possible.

We made choice of about 100 females, afflicted with mental alienation, accompanied with or without rage, having good physical health, subject to the same regimen, and undergoing no particular treatment, as they are regarded incurable. We took down their age, constitution, and temperament, and the state and duration of their menstruation. We chose those that were in separate rooms, and not in the wards, bearing in mind, that in a ward it is only necessary for one to rage to affect the

whole of her companions. We advised them to remain in bed until we had made our visit; this recommendation was not always available, several were too delirious to understand us and to remember our advice; we have not enumerated these in our table, they have only enabled us to prove the state of the pulse during agitation. In fine, knowing that our examinations, repeated for several days only, would not suffice to give an exact means, and in order that we might appreciate the real influence of the temperature, and the possible influence of the moon, or of any other meteorologic phenomenon, we continued them for twenty-eight days consecutively. Before this period of twenty-eight days, we came several mornings to see the patients, and felt their pulse, in order to habituate them to our presence and to our operation.

One period only of twenty-eight days could teach us nothing relative to the influence of the seasons upon the state of the pulse; we recommenced our observations three months after the first, and, this done, we have compared the result.

FIRST PERIOD.

Examination of the pulse made, during summer, on twenty-four insane females, from five to seven in the morning, during twenty-eight days.

SECTION I.

The aggregate number of pulsations varies from one day to another.

The first period of our observations commenced on the 28th day of August, 1831, and terminated on the 24th of the September following. We were always very regular in our attendance on the sick at five in the morning, and at seven our examinations terminated. On the 28th of August we had a hundred patients on our list, on the 24th of September there remained only eighty-nine, those who were missing had either changed their division, or were absent from their chambers at the time we made our visits, which terminated, for them, the course of our observations, or they were so much agitated that we could not, without danger, examine their pulse.

The number of pulsations, counted during a minute, in each of the eighty-nine women, added daily, was, at the termination of the period, 206,436. This total was taken in the following manner:—for the first fourteen days

105,878, for the last fourteen 100,558, a difference of 5,320 for the first fourteen days. In comparing one day with another the greatest difference, in the number of pulsations, took place between the 28th of August, which was the most elevated, and the 24th of September, which was the lowest; on the 28th of August we counted 7,863 pulsations; on the 24th of September 6,910 only, making a difference of 953. The least difference we observed was from the 16th to the 17th of September, this was only of four pulsations.

In order to render our ciphers intelligible, we established proportional means.

The total number of pulsations has given us a mean of 82 and a fraction; what report has it with each of these days? Thirteen days are above and sixteen below. Of the thirteen days of which the pulsations are above the general mean, twelve were during the first part of the period of our examination, or from the 28th of August to the 10th of September inclusive; in the second part of this same period, or from the 11th to the 24th of September, all the quotidian means were below the general mean, with only one exception.

This being established, it remained for us to know if the difference in the number of pulsations depended only on the pulse in certain insane persons, after having been very frequent, returning to a state of calmness, or if we might attribute it to a different number of insane persons participating in the frequency; in other terms, our method represented the intensity of the frequency of the pulse, but it did not represent the number of individuals, who participated of this frequency. This was a fresh question to solve, which we undertook.

The number of additional pulsations, not by day but by patient, gave us a total, representing for each of these patients the sum of pulsations, observed during the twenty-eight days a total, divided by 28, gave a mean which served us as a base whereby to distinguish the days of frequency from those of quiet. The number of pulsations, counted in a minute, during the twenty-eight days, gave, in each patient, a total of 2,487, this divided by 28 gives a quotient of 88 and a fraction. This quotient of 88 we gave as the mean, and we considered as frequent all above that number, and as calm all below it. In one woman the total, for the twenty-eight days, was only 1,481, the mean being 52 and a fraction; we

noted 53 and all above as frequent, and 52 and all below as calm. We acknowledge that, this could only refer to a relative calmness or frequency; we could not pretend to prove any thing farther, being ignorant of the mean of the pulsations of women in health, according to the age, atmospheric temperature, and all other circumstances, which might modify the number.

To the days of frequency of the pulse, thus designated for each patient, we made a daily addition. For the first day of observation, that is on the 28th of August, we had 57 patients above the proper mean, and the last day, on the 24th of September, only 17, and this proportion decreased in a manner corresponding with the intensity of the frequency.

(To be continued.)

THOUGHTS ON THE PRESENT STATE OF MEDICAL EDUCATION,

BY J. C. ATKINSON, ESQ., ROMNEY-TERRACE, WESTMINSTER.

THROUGH the medium of your highly useful publication, whatever has at any period been considered valuable, curious, or interesting in the progress and ameliorations of which medical education is susceptible, you have zealously communicated to the profession,—for this reason have I ventured to request a short space in your Journal.

It may be said that I am merely hazarding an opinion in what I intend laying before you. I shall not certainly presume in self-confidence, but shall suggest what simply appears to me to be feasible. I may therefore premise, in the words of Cicero,—“*Ut potero explicabo, nec tamen quasi Apollo certa, ut sint, et fixa quæ dixero, sed ut unus ex multis probabilia sequens.*” All sciences, it must be granted; are accessible to many false systems, and exposed to many erroneous opinions. Medicine unfortunately is not free from them; but, on the other hand, it seems to demand our most scrupulous attention, especially when we consider the instruction of those who commence its study. All faculties, arts, and sciences are, I think, allowed by the ablest judges, to be unavoidably subject to such changes by time and after improvements, as plainly to render a new system of them equally necessary as useful. The system, then, of educating young

men for the profession of medicine, taken in a comprehensive point of view, must have long been considered as radically bad. Let me speak of the machine as it now works:—a young man is apprenticed to a medical practitioner for five years, in which he is to be taught that which is deemed necessary in the event of his becoming a surgeon;—but, I ask, is this generally or in one instance the case?—What then is the instruction he receives? I answer,—He is employed the full term of five years in the drudgery of the dispensary, or perhaps he is shown how—

To gild a pill, or make a bill,
Or bleed, or blister,
Or how forsooth to draw a tooth,
Or give a clyster.

Thus generally is the period of five years consumed. At the expiration of his apprenticeship he naturally looks at the qualifications necessary to enable him to be a candidate for the diploma; he sees that at least *six* must be passed in the acquisition of medical knowledge; five years are already gone by;—he finds that he has to attend a certain number of lectures of *three and six months'* duration. It is not possible he can do this in one year. He puts on the cap of reflection:—“Five years have I been mixing together the different articles of the Pharmacopœia. I have read much, 'tis true, but I have had no practical instructions: it appears I have still much, very much, to get through before I can think myself competent:—but one year cannot enable me,—I must devote *two or three* years more.” This is the picture that in most cases is presented to us:—what an irretrievable waste of time to the individual who serves a five years' apprenticeship—the most valuable years of a young man's life are thus lost. There can, I think, be none who, unbiassed by prejudice, does not deplore this system. There are but few medical men who possess philanthropy to such a degree as to take much trouble in instructing their apprentices at the bed-side of a patient when opportunities occur. Is it possible that a young man, just released from the pestle and mortar, calling himself a student, on entering a lecture-room or hospital, can derive much advantage from the most celebrated professors of anatomy and physiology. I think he will be

capable of receiving but little instruction, so very different will be the spheres of his actions,—a cold and incompetent auditor, he finds himself transplanted to an unknown soil, he sees everywhere strange objects but half intelligible to him, vague sounds strike his ears, and he just defers to the next year the understanding of a course, which seems as an introduction to all the others. Nevertheless, the silent ever-flowing stream of life passes on, and his loss is irreparable.—Why is this? —To whom does he attach blame?—Can he accuse himself of want of attention?—No: the reason is obvious,—elementary instruction, which has always been considered the first and only source of knowledge has been neglected. He has not been able to avail himself of the experience of his appointed teacher; he has, perhaps, perused and reperused all the works on medicine and surgery, and this he will find to his cost is far removed from sufficiency. How is this deplorable system to be abolished?—In what manner can we recommend medical instruction to be imparted? Allow me to suggest the following method:—Let two years, which I consider sufficient, be devoted to pharmacy and the business of the dispensary, the remaining four years to attending lectures and hospital practice, receiving at the same time the benefit of visiting the patients of a certain rank of the practitioner with whom he is apprenticed. He will then discover that, to be proficient in medicine, he must *see* every operation relating to surgery performed,—he must *see* patients labouring under all the various ills that flesh is heir to, to be able to recognise one symptom from another.

My cordial wish is for the welfare of the profession, of which I am an humble member. I sincerely hope that we shall yet see great alteration in medical education, a point desired by all; but let all things be done with the utmost caution,—“*præusquam incipias consulta, et, ubi consulueris, mature facto opus est,*” says Sallust.

NOTE FROM DR. EPPS.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—In the report of the Westminster Medical Society in your Journal of Dec. 7th, you make me to say that “I am under no

compliment to the Company of Apothecaries, as they refused to recognise my lectures on the Practice of Medicine until I became a member of the College of Physicians.” What I stated was this:—That though the Apothecaries’ Company recognise my lectures on Chemistry, Materia Medica, and Botany, yet, if I wished to lecture on the Practice of Physic, they would not recognise these lectures, because I have not joined the College of Physicians.” The passage, as it stands, intimates that I have lectured on the Practice of Physic, which I have not; and also, that my lectures are not recognised. As neither is correct, and as the impression from the passage might lead some to suppose that I lecture on a subject on which my lectures are *not* recognised, which is not the case, I request your insertion of the accompanying.

Yours in well wishing,
JOHN EPPS, M.D.

89, Great Russell-street,
Dec. 17th.

[The words of the report were strictly correct. If Dr. Epps mentioned the subjects on which he lectures, they escaped me.—REP.]

Reports of Societies.

ROYAL SOCIETY.

[THE following notices of papers lately read before the Royal Society, are taken from the official summary drawn up for the use of the members.]

The Anatomy and Physiology of the Liver.
By FRANCIS KIERNAN, Esq. M.R.C.S.

After giving a short account of the descriptions of Malpighi and other writers, respecting the minute structure of the liver, the author proceeds to state the results of his own investigations on this subject. The hepatic veins, together with the lobules which surround them, resemble in their arrangement the branches and leaves of a tree; the substance of the lobules being disposed around the minute branches of the veins like the parenchyma of a leaf around its fibres. The hepatic veins may be divided into two classes; namely, those contained in the lobules, and those contained in canals formed by the lobules. The first class is composed of interlobular branches, one of which occupies the centre of

each lobule, and receives the blood from a plexus formed in the lobule by the portal vein; and the second class of hepatic veins is composed of all those vessels contained in canals formed by the lobules, and including numerous small branches, as well as the large trunks terminating in the inferior cava. The external surface of every lobule is covered by an expansion of Glisson's capsule, by which it is connected to, as well as separated from, the contiguous lobules, and in which branches of the hepatic duct, portal veins, and hepatic artery, ramify. The ultimate branches of the hepatic artery terminate in the branches of the portal vein, where the blood they respectively contain is mixed together, and from which mixed blood the bile is secreted by the lobules, and conveyed away by the hepatic ducts, which accompany the portal veins in their principal ramifications. The remaining blood is returned to the heart by the hepatic veins, the beginnings of which occupy the centre of each lobule, and when collected into trunks pour their contents into the inferior cava. Hence the blood which has circulated through the liver, and has thereby lost its arterial character, is, in common with that which is returning from the other abdominal viscera, poured into the vena portæ, and contributes its share in furnishing materials for the biliary secretion. The paper is accompanied by numerous drawings of preparations made by the author, of the minute structure of the liver, in which the different sets of vessels and ducts were injected in various ways.

On the Reflex Function of the Medulla Oblongata and Spinalis. By MARSHALL HALL, M.D., F.R.S. L. & E.

The author, after commenting on the opinions of Le Gallois and Cruveilhier relating to the functions of the spinal marrow, adverts to a property or function of the medulla oblongata and spinalis, which he considers as having escaped the notice of these and all other physiologists; namely, that by which an impression made upon the extremities of certain nerves is conveyed to these two portions of the nervous system, and reflected along other nerves to parts different from those which received the impression. He distinguishes muscular actions into three kinds: first, those directly consequent on volition; secondly, those which are involuntary,

and dependent on simple irritability; and thirdly, those resulting from the reflex action above described, and which include those of the sphincter muscles, the tonic condition of the muscles in general, the acts of deglutition, of respiration, and many other motions, which, under other circumstances, are under the guidance of the will. Volition ceases when the head or brain is removed; yet, as he shows by various experiments, movements may be then excited in the muscles of the limbs and trunk, by irritations applied to the extremities of the nerves which remain in communication with the spinal marrow; but these actions cease as soon as the spinal marrow is destroyed. Hence the author concludes that they are the effect of the reflex action of the spinal marrow, which exists independently of the brain; and, indeed, exists in each part of the organ independently of every other part. He considers that this reflex function is capable of exaltation by certain agents, such as opium and strychnine, which in frogs produce a tetanic and highly excitable state of muscular irritability. Hence he is led to view the reflex function as the principle of tone in the muscular system. He considers that certain poisons, such as the hydrocyanic acid, act by destroying this particular function. The effects of dentition, of alvine irritation, and of hydrophobia, of sneezing, coughing, vomiting, tenesmus, &c. &c., are adduced as exemplifications of the operation of the same principle when in a morbid state of exaltation.

Respiratory Organs of the Leech. By GEO. NEWPORT, Esq.

The stomach of the leech has been hitherto described as a large elongated sac, simply divided into ten compartments by perforated membranous partitions; but the author, by a more accurate examination, finds that each portion of that organ is expanded into two lateral cæca, which increase both in size and in length as they are traced along the canal towards the pylorus. The cæca belonging to the tenth cavity are the longest, extending as far as the anus, and have themselves four constrictions; the cavity itself terminates in a funnel-shaped pylorus. When the posterior end of the animal is cut off, the cæcal portions of the stomach are laid open, and the blood which it receives flows out freely, as fast as it is swallowed; and hence the leech, under

these circumstances, continues to suck for an indefinite time.

The respiratory organs consist of two series of pulmonary sacs, arranged along the under side of the body, on each side of the nervous cords and ganglia. They each open upon the surface of the body by a very minute but distinctly valvular orifice. The membrane which lines them appears to be continuous with the cuticle, and is exceedingly delicate and highly vascular, receiving the blood, for the purpose of its being aerated, from the veins of the system. The blood is returned from these sacs into the lateral serpentine vessels by vessels of a peculiar construction, passing transversely, and forming loops, which are situated between the cæca of the stomach, and which are studded by an immense number of small rounded bodies, closely congregated together, and bearing a great resemblance to the structure of the venæ cavæ of the cephalopodus mollusca. The purpose answered by this structure is involved in much obscurity; the author offers a conjecture that they may be analogous in their office to the mesenteric glands of the higher animals.

With a view to determine some circumstances relating to the mode of the respiration of the leech, the author made some experiments, by confining the animal in water deprived of air by boiling. After some time the leech was observed to give out bubbles of air; and the water of the vessel, when tested by lime water, indicated the presence of carbonic acid.

The paper is accompanied by drawings of the structures described.

HUNTERIAN SOCIETY.

December 13th, 1833.

C. A. KEY, Esq. President, in the Chair.

Scarlatina.

IN reference to the minutes of the preceding meeting, of which an abstract is given in our journal of Dec. 7th,

Mr. Beale remarked, that when residing at Stratford, scarlatina had occurred in a very severe form. He lost three children in one family under a train of symptoms similar to those which had characterised the fatal cases related at the last meeting. There was smothered heat, faint eruption, enlargement of glands, and muttering delirium. He, at this

time, had adopted the opinion that ammonia was a specific, that it supported without stimulating; but it had disappointed his expectation in these cases, and in other severe cases in which he employed it. Where there is a confused state of head, and muttering delirium, he thought ammonia did harm.

The President inquired whether the severity of epidemic scarlatina depends on the poison, or on the state of the constitution.

Dr. Babington believed that most depended on the state of the person, owing to occult causes in the constitution and atmosphere.

Dr. Ashwell thought that more was attributable to the poison than to the constitution, and that this gave a character to the epidemic. He had seen delicate children attacked and go mildly through the disease, whilst stronger children suffered severely. Analogy led to the same conclusion as in puerperal fever, which occurs after good and bad labours, and is not dependent on constitution.

Mr. Bevan took a different view of the circumstances. Several children of the same family might be seized, some having the disease severely and others mildly, which he thought would not happen, were the severity dependent on the quality of the poison.

Mr. Beale entertained the opinion, that much depended on the character of the epidemic. A year and a half ago he attended a child who died of scarlatina. He himself took the infection, and imparted it to his children and servants, and all had it severely. He thought this tended to show that the degree of severity depends greatly on the character of the existing epidemic.

Dr. Uwins adverted to a variety of facts which indicate atmospheric influence on disease. As to the treatment of scarlatina, he considered the circumstances stated by Mr. Beale as being opposed to the use of ammonia as specially calling for its use. There is, said he, debility and oppression of power, an asthenic state with erythematic irritation, and ammonia is one of the best remedies. He considered the agency modifying the severity of the disease, as in the atmosphere, acting on constitution, the poison being the same.

Mr. Greenwood maintained, as to treatment, that it must vary according to circumstances; there will sometimes be active fever when antiphlogistic means will be indicated, at other times ammonia will be required.

Dr. Babington believed that no one remedy could be relied upon in these cases, in which there is something specific accompanied with the varying symptoms and type of fever. Most of the fatal cases he had seen had proved so from local swelling. The blood vessels were pressed upon, and great cerebral congestion induced. In the case of his own child, the fatal termination arose from this cause—not from internal swelling, but external: the tonsils, however, were ulcerated. Under these circumstances, he conceived that ammonia was little likely to do good, but rather, as being a stimulant in the throat, would act injuriously. He adverted to another instance, in which the topical swelling seemed to put an end to remedies—there did not appear time for them to act.

Dr. Ashwell related a case, in which the internal swelling was such that the aperture was not larger than a crow-quill, attended with high fever. He gave ammonia freely, applied nitrate of silver in solution to the fauces, and mustard poultices to the throat and feet, and the child recovered.

The President inquired the precise state of the swollen parts,—whether common inflammation, or ulceration, or infiltration.

Mr. Beale said, that in the cases he had related the glands were much swelled, and were hard and tense, as if from infiltration.

Mr. Greenwood believed, that in different cases all the conditions mentioned by Mr. Key might be found. He mentioned an instance, in which an entire tonsil sloughed out before the patient died.

Mr. Bevan reported an instance in which a submaxillary gland sloughed, and the coat of an artery ulcerated, so that the child bled to death.

Dr. Conquest had seen a considerable number of cases of scarlatina during the present epidemic. He found local depletion, followed by blisters, ammonia, and quinine, the most successful treatment.

Mr. Cooke directed the attention of the meeting to the "crowing convulsion," or spasmodic croup of infants. He said, that he had formerly brought this subject before the Society, in connexion with a case in which he found inflammation and abrasion of the lining of the epiglottis. Several gentlemen who were then present expressed their belief that the disease was seated in the head, and that the

spasm of the larynx was merely sympathetic. He had just met with another fatal case. The child was nine months old, still at the breast, and had cut no teeth, and when brought to him a fortnight ago, had been suffering for some time from the suffocative attacks, though with less severity. There was an unhealthy condition of the excretions from the bowels, but not the least indication of head disorder. He prescribed a grain of calomel every other night, and rhubarb and magnesia in the day, and divided the gums. The symptoms rapidly grew worse. Two leeches were applied to the larynx, and a blister to the sternum, and half a grain of calomel given every four or six hours. Three or four days before death the spasms became so frequent as to cause almost continued difficulty of respiration, and in this stage signs of head affection arose. Leeches were applied to the temples, but nothing arrested its progress. On examination, the mesenteric glands were found somewhat enlarged; the lining of the epiglottis was inflamed and thickened. Just within the larynx the mucous membrane appeared healthy for about half an inch, but down the trachea it was inflamed. The specimen was exhibited: the larynx and trachea were filled by a puriform fluid. There was not the least deposition within the ventricles or on the surface of the brain, and it was even doubtful whether there was heightened vascularity. If it were so, he thought it not more than might be expected from the difficulty of respiration.

Dr. Hodgkin thought the disease not so much one of the head as of the throat. The membrane is evidently inflamed and thickened. The upper part of the throat in children, he remarked, is very irritable, and the head becomes affected by many causes of irritation.

It was announced that the meeting would now be adjourned till the 8th of January.

MEDICAL SOCIETY OF LONDON.

Monday, December 16, 1833.

WILLIAM KINGDON, Esq. in the Chair.

Most extraordinary Case—A Case in which a common Earthenware Egg-cup was found in the small Intestines.

MR. DENDY brought before the notice of the Society the following singular case:—A man, aged 60, came into Christchurch workhouse

with scrotal hernia, which had existed thirty-five years, but was partially reducible. He had been for some time subject to repeated attacks of chronic diarrhoea and dysentery, and ten weeks previous to his death he had diffused peritonitis. About three weeks previous to that event he was seized with stercoraceous vomiting, and the taxis was applied, but was not perfectly successful, as a small tumour still remained, similar in appearance to a knuckle of intestine. The symptoms continued, and on the 4th of December he died.

About twelve hours after death, Mr. Dendy, in the presence of Mr. Stevens and Mr. Brown, proceeded to examine the body. The stomach appeared to have suffered from inflammation, and the pyloric orifice could be distended with the greatest facility; the small intestines were matted together, and their coats were so attenuated, that they formed a perfectly diaphanous membrane. The ileum was of a purple colour, and marked in some places with little patches of ulceration; in the interior of this intestine, about ten inches from the ileo-colic valve, was found a common-sized earthenware egg-cup, resting upon the lumbar vertebrae, near the posterior superior part of the crest of the ilium; the mouth of the cup was in the direction onwards, towards the large intestines, and its interior was stained of a black colour. No portion of intestine was found in the hernial sac, but there was a chocolate-coloured fluid, similar in appearance to decomposed intestine in it. The ileo-colic valve was perfectly healthy, and of its natural size; and, although the colon and rectum were traced throughout their whole course, no marks of disease could be discovered; the cæcum was found full of scybala. The deceased had been much addicted to drinking, but had never exhibited any symptoms of insanity; nor did Mr. Dendy, from any part of the man's conduct, although he had been under his observation some time, expect to find such a source of disease. He was of opinion that, from the healthy state of the large intestines and the valve, and the diseased condition of the smaller ones, that the cup must have passed by the mouth. The portion of intestine which had formed the hernia was below the cup.

Mr. Salmon could not think that this body had passed the pylorus; it would probably have suffocated the man. He had, however,

seen many instances where patients had confessed to having passed foreign substances through the anus: it might by possibility pass the valve of the colon, but could not, in his opinion, pass by the mouth.

Mr. Stevens thought that if the cup had entered into the stomach, it might with facility pass the pyloric valve, which was so unusually large: the state of the intestine led him to suppose that it had passed in this way.

Mr. Hooper mentioned a case which occurred at St. Bartholomew's Hospital, in which a six-ounce bottle had been passed into the rectum. Mr. Lawrence was sent for, and on his arrival proceeded to dilate the anus with his fingers, and finally succeeded in extracting the foreign body.

Dr. Ryan remarked that if this man were subject to delirium tremens or melancholy, he considered it probable that he might have swallowed the egg-cup when his mind was much affected. He mentioned the circumstance of Gosse, of Geneva, having swallowed metallic balls of two inches and a half in diameter.

Mr. Headland made some remarks as to the fact, that the egg-cup was not acted on by the gastric fluid.

Dr. Severn observed that the cup was made of silex, which was not soluble in the strongest acids, and it was then glazed with cobalt with the same intention.

Mr. Kingdon said that he had seen a man nearly killed by swallowing a shilling, but that eventually it passed by the rectum.

Dr. Ryan, Mr. Hooper, Mr. Dendy, and Mr. Salmon mentioned cases in which farthings, halfpence, pence, and sovereigns were swallowed without having produced any bad effect.

Several other members spoke as to the probability or improbability of the cup having passed by the mouth, after which the Society adjourned until next Monday.

WESTMINSTER MEDICAL SOCIETY.

Saturday, December 14, 1833.

Dr. COPLAND in the Chair.

Medical Reform—One Faculty at Medicine.

A WARM discussion took place on Dr. Gregory's amendment, which Professor Burnett, who was chairman at the preceding meeting,

declared to have been lost, but in accordance to the laws of the Society was now to be submitted to the ballot. The original motion for one faculty by Dr. Johnson was carried at the last meeting; but, as some of the members considered it to be irregular before the amendment was finally disposed of, both were now re-considered, and both were lost.

Dr. Johnson then related the case of a young lady who was disappointed in marriage, fell into atrophy, and died without the manifestation of any particular disease. This showed the vast influence of the mind over the body.

Mr. Pettigrew related cases of small pox, in which the head was shaved, and the new crop of hair was of darker colour, though the original hair was red.

The meeting then adjourned.

LONDON MEDICAL ASSOCIATION.

The members and friends of this Institution dined together on Thursday week at Radley's Hotel, Bridge-street, Blackfriars, Dr. Ryan in the Chair, and Mr. Hunter Vice-President; on which occasion several admirable speeches were delivered, and the utmost harmony prevailed. Great praise was justly given to the stewards, Mr. Garrett and Mr. Churchill, for the excellent arrangements they had made. This Society has been recently established at the Gerrard-street Medical School, and enrols among its members not only the numerous students of that school, and of others in the west end of the town, but also many practitioners. It is well calculated to enlarge the minds of students, and the discussions are conducted with moderation, friendly feeling, and good fellowship. The admission fee is trifling. The Association meets every Tuesday evening, at nine o'clock, immediately after Mr. Wade's lectures on morbid anatomy.

At the meeting of Tuesday, Dec. 17, 1833,

DR. RYAN in the Chair,

*Ganglion Oticum—Cynanche Tonsillaris—
Tobacco in Croup.*

Mr. Turnham presented to the notice of the meeting two preparations illustrative of the ganglion oticum, one from a child of a day old, the other from an adult. He observed, that having read a paper on the subject last

summer, which he extracted from the Edinburgh Medical and Surgical Journal, he was much disappointed in a short time afterwards by a paper published in the Medical Gazette by Professor Mayo, in which that learned gentleman stated that he and Mr. Partridge had failed to discover the ganglion in two subjects. Nevertheless, he, Mr. Turnham, was determined to investigate the subject, and was happy to exhibit to the meeting the result of his labours. It would appear, by comparing the preparations with the original drawings, that the similarity was established.

Mr. Harewood then read a communication from Dr. Epps on cynanche tonsillaris, which elicited several remarks.

Mr. Duncan related a case of cynanche trachealis in a lad aged 14 years, which was seen by three experienced practitioners, in which he used eight ounces of an infusion of tobacco, containing half a drachm of the latter; and this induced vomiting and purging, and the expulsion of a considerable portion of adventitious membrane. He had given the same remedy of half the strength in the case of a child aged eighteen months with the happiest effect, and was resolved to try it in future.

Mr. Crouch, Mr. Davis, Mr. Churchill, Mr. Harewood, and others, made several judicious observations on these cases.

The Chairman followed, and explained the dangerous effects of tobacco on the animal economy. He cautioned the meeting not to adopt the practice so enthusiastically advised by their friend; as all young practitioners were too ready to believe that the success of a remedy in a few cases was sufficient. He gave a minute description of the progress and pathology of cynanche trachealis, and proved that tobacco was not a safe or a successful remedy in many forms of the disease; as, for example, when the adventitious membrane firmly adhered to the trachea, and descended into the bronchial tubes. He thought the exhibition of tobacco to infants and children highly dangerous; and had not purging occurred in the case alluded to, and the remedy been thrown off, the worst effects might have followed.

A vote of thanks was then returned to Mr. Turnham, and the meeting adjourned to that day fortnight,

THE
London Medical & Surgical Journal

Saturday, December 21, 1833.

MEDICAL REFORM.—WESTMINSTER
MEDICAL SOCIETY. — UNIVERSITY
OF CAMBRIDGE.—FACULTY.

THE valuable proceedings of the Westminster Medical Society, on the subject of Medical Reform, have, at length, closed with a resolution to petition the House of Commons, for an inquiry into the state of the profession. In not pledging itself to demand from the Legislature, at the present moment, and without further inquiry, any specific measures of Reform in detail, we think the Society has acted wisely. A simple enumeration of the abuses which prevail, to whatever causes they are to be traced; whether to the incorrigible temper of the medical corporations, or to the actual inefficiency of the law:—their simple enumeration, we repeat, is sufficient to exact the attention of the Legislature to its prayer for inquiry:—till that be instituted, under the sanction of Parliament, it seems premature to decide upon the remedy. When the nature and extent of the abominations of the present system, if system it can be called, which system hath none, are thoroughly searched and compared, every man will be enabled to rise from the consideration of his own grievance to those of the general commonwealth of medicine; and we do not hesitate to predict, there will then be much greater unanimity in the profession, as to the necessary reforms, than can be expected in the present state of the inquiry—when we are but at the beginning of the end. Unless this unanimity be secured, nothing is attained; the profession cannot be satisfied by any partial manner, or bit-by-bit Reform.

When the Legislature shall force that secrecy, the screen of corruption, which the College of Physicians, for instance, imposes by a by-law upon its Fellows,—which all corporations practise, without a law, to hide their misdeeds, we have no doubt that things will come to light, which it hath not entered into the heart of the uninitiated to conceive, and that conviction will flash upon the most incredulous, who fondly hope any thing good can come out of these public nuisances, in their present constitution. It is the drift of those, who are struggling to retain their unlawful monopolies, themselves or their agents, to sow dissension, if possible, among the friends of Reform, by forcing an untimely discussion of its detail;—and then how loudly will they urge the inconsistency of the public demands as an objection to substantial Reform,—to any Reform but what emanates from their mere pleasure.

Within the last fortnight we have had, by way of lesson, a striking example of the uncompromising spirit which animates those public bodies, whose fatal influence over the medical profession we have to lament. We beg to call to the recollection of our readers, that an attempt to open the University of Cambridge was lately made by some public-spirited gentlemen; true to its principles of religious intolerance, that body refused to inquire into the propriety even of dispensing with its religious test of literary proficiency. The *religio socii* still rests upon the rock of orthodoxy, and *Mater Academia* richly deserves the honour she receives from her worthy offspring*. Such a determination

* In Dr. Ferris' very able work, *A General View of the Establishment of Physic as a Science in England*, Longman, 1795, we find the following extract from the statutes of the college. "Si Doctoris gradum in aliqua

of one of our national Universities, commonly, too, reputed the most liberal, to resist the spirit of the times, speaks trumpet-tongued for the necessity of rejecting the influence of those bodies altogether upon the medical profession. They have long ceased to be schools of medicine:—the science naturally follows the haunts of men; and they have shown such a determined bigotry to warp their privileges to ecclesiastical purposes, that it is but just to leave them to the full enjoyment of their pious purposes, and to rescue medicine from being hedged in by their *divinity*. If, indeed, their influence was as limited in medicine as it is in the sister profession of the law, we should not, for our part, complain. In the latter profession, the student is saved a portion of his probationary time, and the payment of some caution money, by an Academic degree; but in other respects the highest honours of professional rank are open to every practitioner, and instances are not wanting of men, not uneducated though self-taught, who had never seen the Universities, rising from the level of an attorney's clerk to the top of their profession. In the profession of the Bar we hear of no jealous distinctions; every man enjoys the same rank:—distinctions do indeed and must exist;—men are as unlike in their minds as in their faces; and where the natural buoyancy of talent is allowed to exert itself, the *gifted* man has no dread of being undistinguished in the herd. But shall we argue from the existence of this natural superiority of man to man, for the maintenance of factitious ranks, which are founded on the possession of no superior qualifications, natural or ac-

quired. In latter times, the abettors of the College of Physicians rest their case upon the supposition of the higher literary merits of the English University doctors. There might, indeed, be a presumption in their favour if the Universities were open to all the world, like that of Dublin. And perhaps the evidence of a few years' application to liberal studies is a more satisfactory test of education, or, what is better, of mental discipline, than a merely formal examination, for which the student may be crammed at a moderate rate by any advertiser. We are far from being desirous to dispense with preliminary education, and there is no profession which stands more in need of it than medicine. On the contrary, we demand a higher education, both literary and professional, from every candidate, before he is admitted into the ranks of the profession; for it is really disgusting to see the books, which are daily published, to vamp the gross ignorance of those whom it is the short-sighted policy of the governing powers, to admit into the *emoluments* of the profession. There was, however, an earlier period, at which the College spoke the language of sincerity and monopoly, and boldly declared, that it was resolved "to protect the profession from the invasion of the vulgar, which hath been the usual support of the younger sons of the gentry of this kingdom *."

The Society, by its vote last evening, discountenanced the insidious embryo job of a Board of Commissioners, under the direction of the Home Secretary, and refused its sanction, in the present state of the question, to the institution of One Faculty of Medicine for the whole kingdom. The former of these measures, to

nostram academiarum susceperit, *honoris causa*, sedate decenter examinandus, ne quid indignum pati nostram examinationum formam academia videatur."—p. 95.

* See "a Short Account of the Institution and Nature of the College of Physicians," published by the College. Brit. Mus. Lib.

every independent mind, was plainly objectionable; upon the latter there is considerable diversity of opinion, both as to its meaning and its propriety, or rather feasibility. Our contemporary, *The Lancet*, who has the merit, perhaps, of suggesting part of the title of this proposed new College of Medicine, has, nevertheless, been more liberal in the numerical part, and has maintained the necessity of a Faculty for each of the three great divisions of the United Kingdom; a proposition certainly not liable to the objection of inconvenience, which lies to Dr. Somerville's scheme, if Dr. S. intended, as we presume he did, that this Faculty should have its seat in the capital of the kingdom, and that all aspirants for its degree should come to London to be admitted. Nor is the scheme objectionable for its inconvenience merely,—we apprehend it trenches upon the national feelings of the sister kingdoms; and however desirous some of the Irish or Scotch may at present be to escape the rigour of their national schools, and graduate in London, as now-a-days to pass at the College of Surgeons, neither class of these patriotic people, we have reason to think, would consent to merge their native schools in the one London Faculty. To the *Medical Gazette* the notion of a Faculty, whose functions should by implication supersede its beloved Colleges, and their lovely train of ranks, dependencies, and jobs, is revolutionary, and that of one Faculty, whilst our French neighbours have recommended the establishment of *six*, preposterous. As there seems to be a magic in this word *Faculty*, it may be as well to strip it of its cabalistic effect. A Faculty is neither more nor less than the body of masters and professors of any science; and, in recommending the establishment of *six*, in place of three Faculties, in France, the

Academy of Medicine has had no other object than to consult the convenience of the students of medicine in that large kingdom, by appointing their place of study at a reasonable distance from their homes.

For our parts, we do not think that names, like women, are the worse for being old; physician and surgeon are very good names:—but we have a violent affection for principles; and our principles are these, that any distinction in the professional education of a physician and surgeon is absurd, a proposition which does not interfere with the separate practice of these arts by the more experienced practitioners:—that the *half knowledge*, which is required of practising and compounding apothecaries is an insult to common sense, and injurious to the science; that the distinction of Fellows and Licentiates originates in usurpation, and is supported for the selfish purposes of an insolent monopoly: that all these evils are to be encountered by the establishment of uniformity of education, uniformity in rank, and uniformity in rights throughout the whole kingdom. We refer our readers to the Report of the Academy of Medicine in France, to be published in our next number, in support of these principles; we have already given an epitome of its contents,—but it does appear to us to touch so precisely upon some of the greatest defects of our own medical constitution, that we have thought it right to place it at length before the profession.

MEDICAL REFORM.—MEETING OF
THE PROFESSION AT SHEFFIELD.

At a general meeting of the medical profession of Sheffield, held at the Savings' Bank, Dec. 2nd, 1833, CORDEN THOMPSON, M.D. in the chair, the following resolutions were passed unanimously.

Proposed by Mr. Boulton, seconded by Dr. Holland :—

“ Considering the improved, and daily improving state of medical science, the great enlargement of its boundaries, the brilliant progress of our continental brethren from the superiority of their medical regulations and institutions, together with the liberal views and sentiments now so generally prevalent throughout the profession, it is the opinion of this meeting, that the existing medical incorporations of the United Kingdom are altogether inadequate to the extended and growing wants of the profession and the public ; such incorporations being either radically defective in constitution, and arbitrary and unjust in operation, or antiquated and insufficient for the advancement of the healing art, and the effectual prevention of empiricism.”

Proposed by Mr. Gillott, seconded by Dr. Favell :—

“ That it is intolerably grievous, and flagrantly unjust, for the regular practitioner to be compelled by medical corporations to incur great expense, and consume much time and labour in qualifying himself for the duties of his vocation, whilst these same corporations have neither the power nor the pretensions to protect him against the encroachments of the most notorious empirics, and the various unlicensed practisers of medicine with which every town in the kingdom swarms.”

Proposed by Dr. Harwood, seconded by Mr. Green :—

“ That the absurdity and evils of the present system of medical regulations are strikingly illustrated by the fact, that a practitioner, educated and duly licensed by one corporate body, can be precluded by another from exercising his profession in certain towns and districts over which such body holds jurisdiction ; and that that it is preposterous and unjust in the extreme for this jurisdiction to be exercised by men professedly deriving their education from universities, where proper scientific and practical medical instruction and examinations are *absolutely unknown* ; as is the case, for example, with the Fellows of the London College

of Physicians ; and that such a system tends simply to monopoly of practice and individual aggrandisement, at the expense of the interests of the public, and the profession in general.”

Proposed by Mr. Wm. Jackson, seconded by Mr. E. Gillott :—

“ That the present constitution of the London College of Surgeons, by which the self-election, self-perpetuation and irresponsibility of its managing council is permitted ; the hospital appointments, moreover, and lectureships, which the members of this council hold, and their power of rejecting any educational testimonials from other teachers, are circumstances totally irreconcilable with the due advancement of the profession, and the rights of every member of the college.”

Proposed by Mr. Walker, seconded by Mr. J. F. Wright :—

“ That it is utterly derogatory to the character and dignity of the profession, for the regulation of medical practice and education to be in the hands of an avowedly trading company.”

Proposed by Mr. Green, seconded by Mr. Wilson :—

“ That in the opinion of this meeting, the entire system of medical education and apprenticeships, as well as that of licensing practitioners, urgently demands revision, the present mode of licensing by various distinct bodies, with professedly distinct views, and yet all for a similar purpose ; as, for example, by the universities of Oxford and Cambridge, by the Royal Colleges of Physicians and Surgeons, and by the Company of Apothecaries in England and Wales, and by the various other Colleges and Faculties in Scotland and Ireland, is not only irrational in itself, but mischievous in its effects, and is especially grievous to the members of the profession, inasmuch as certain licentiates claim exclusively offices, privileges, and distinctions, with their attendant honours and emoluments, to which they have no reasonable pretensions or rights beyond the rest of their medical brethren.”

Proposed by Dr. Favell, seconded by Mr. Turton :—

"That since it is impossible for all these separate bodies, possessing distinct and separate interests, and regarding each other frequently with jealousy, and even disrespect, cordially to unite and co-operate in forwarding the public good and the advancement of the profession, this meeting considers that one Faculty, or Academy of Medicine, alone should be established in each of the three capitals of these realms, for the purpose of regulating medical practice and education, which it is advisable to reduce to one uniform standard throughout the empire."

Proposed by Dr. G. C. Holland, seconded by Mr. E. Thompson:—

"Deeply impressed with the importance of the medical charities of this country, in reference to science and humanity; and viewing the exclusive system in some, and the abuses in all, relative to the election of medical officers, this meeting is of opinion, that all such elections should take place by public competition, before a duly constituted medical tribunal; and, further, that, as in other countries, the general medical management of such charities, in all matters touching the promotion of medical science and education, should be under the direction of the aforesaid Academy of Medicine, subject to the controul of the legislature, in order to their being rendered as extensively useful as possible to the student, the profession, and the public at large."

Proposed by Mr. Wright, seconded by Mr. Richardson:—

"That a petition embracing the substance of the foregoing resolutions, and also praying for a committee to inquire into the general state of the profession throughout the United Kingdom, be drawn up for presentation to the House of Commons."

Proposed by Mr. G. Turton, seconded by Dr. Harwood:—

"That this meeting does hereby earnestly appeal to all members of the profession generally, and urgently call upon them to come forward with promptness, and to aid by every means in their power in promoting a grand national medical reform, worthy of themselves and of the country to which they belong."

Portuguese Hospital Reports.

(Continued from page 636.)

Gun-shot Wound of the Chest.

D. S., a major in the service of her Majesty Donna Maria, was shot through the left side of the chest in the sortie of the 24th of March. He was a man of about 32, of rather irregular habits, but of good general health. The ball (musket) entered the anterior and upper part of his chest, shattering the third rib near its sternal end, and made its exit close to the spine, to its left side, and in the region of the tenth rib, which it also fractured. Considerable hæmorrhage followed the infliction of the wound. During the ten days that he survived he suffered considerably from severe pain in his chest, great difficulty of breathing, and distressing cough and hiccups. Air rushed in and out through the exit of the ball with the contraction and dilatation of the chest. He was bled freely and repeatedly, and the antiphlogistic treatment in other respects was pursued to every warrantable extent.

The constant and great irritability of this patient, and my visits to him being those of a looker on only, I was obliged to refrain from any stethoscopic examination.

Autopsy six hours after Death.—The ball had passed through the outer and lower part of the superior lobe of the lung, almost grazing the heart. In the upper part of the chest the pleura had contracted very strong adhesions. The cavity of the chest contained a good deal of matter mixed with blood. The substance of the lung and the pleura were highly inflamed. The ball in shattering the third rib had driven into the chest some portions of bone, which by their irritation had caused a deep cavity in the substance of the lung, near the entrance of the ball. There was no matter in this cavity, and it was large enough to contain half an ounce of liquid.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Gonorrhœa—Enlargement of the left Nympha—Nymphotomia.

A YOUNG woman, æt. 25, was admitted, under Mr. Lawrence, with gonorrhœal discharge and

enlargement of the left nympha. The latter disease has existed for a long time, and has been a very great inconvenience to her. On Monday Mr. Lawrence removed the enlarged mass with a small knife. The patient seemed to suffer great pain, but her sufferings were short, as Mr. Lawrence removed the portion in six or seven seconds. On examination, it appeared highly vascular.

WESTMINSTER HOSPITAL.

Herpes.

In a case of herpes in a female, at present in the hospital, Mr. Guthrie has employed the acetate of copper, as an external application, with very decided success. This ointment was originally employed by an old woman, who, about thirty years ago, undertook to cure some very severe cases of herpes at that time in the hospital. Her treatment was completely successful, but she refused to divulge the nature of the ointment. It was, however, analysed, and found to be composed of acetate of copper. Ever since that period the acetate of copper has been applied in like cases with uniform success.

Burns—Application of Flour—Cure.

In two cases of burns (occurring in young children) which were lately admitted into the hospital, the application of flour has been attended with the most favourable results. Mr. White strongly recommends this mode of treatment, when the burn is not deeper than the cutis. The instantaneous good effects of dredging with flour are really surprising; on its application to the parts affected the pain is instantly removed and the patient, from being in a state of agony, is completely free from uneasiness.

ST. GEORGE'S HOSPITAL.

Tumour of the Arm.

A man was admitted, several months since, with a tumour, of the size of a large egg, situated under the biceps muscle of the arm. It was moveable, and gave him no pain, with the exception of a slight feeling of numbness in the fingers of the hand of the same side. Handling the tumour gave him no pain, and the contraction of the biceps muscle over it tended somewhat to fix it. It was very carefully examined several times by the surgeons of the hospital, who gave it as their opinion, in conjunction with Mr. Brodie (under whose care the man was placed), that the tumour was of a malignant nature, and that extirpation was the only remedy that presented itself.

A few days after the last consultation on the case, the operation of removing it was performed by Mr. Brodie. An incision was made through the skin and cellular texture covering it, which were dissected off on each side with great care. In the course of the dissection, it

was found to extend deeper in among the muscles than the external examination of it led the surgeons to believe. The trunk of a considerable nerve ran through the substance of the tumour, which was divided, as were the fibres of the muscle in which the malignant structure was imbedded. Great care and minuteness of dissection were required in dissecting out the tumour to avoid wounding any of the large nerves and vessels running through the diseased cellular structure covering it. In the course of the operation, a large branch from the humeral artery was divided and immediately secured. The operation occupied about twenty minutes.

On examining the structure of the tumour, it was found to be of a nature between scirrhus and fungus hæmatodes. The man recovered from the effects of the operation without any bad consequences resulting, or any unfavourable symptoms showing themselves, and he left the hospital perfectly well. Some short time since, however, he again came back to the hospital with another tumour of an apparently similar nature to the former one, and situated nearly in the same situation. The former tumour having been found, on examination, to be of a malignant growth and structure, it was intimated to the patient, by Mr. Brodie, that the only way effectually to get rid of it was to amputate the arm at the shoulder-joint, to which the patient, we believe, consented, and the operation was to have been performed by Mr. Brodie, when the patient received a letter from his friends in the country, stating that "there was a clever doctor down their way who cured cancer and such like, and bade him come down and be cured likewise." The patient very naturally left the hospital to see what chance the bumpkin could give him, and we have not yet heard of the result.

Sloughing Sores of the Back.—Benefit of Dr. Arnott's Water Bed.

There is at present a man in Egremont Ward, who has been in the hospital for some time, with extensive sloughing sores about the back, sacrum, ilia, &c., and which have taken on a kind disposition to heal ever since he has been placed on one of Dr. Arnott's water beds. These beds are not, however, in very great repute at St. George's; one of them broke a short time since, and the patients who use them generally complain of the excessive dampness and diaphoresis which they cause. Mr. Brodie's opinion, too, is rather against their utility; the necessity of the changing the water frequently, and the undulatory motion which the water gives to the patient upon his moving ever so slightly, are so many arguments, Mr. Brodie believes, against their practical utility. Whether these considerations, however, be true or false, it is perfectly certain that this patient has improved greatly since he has been placed on a water bed.

Sloughing of the Penis, Scrotum, and neighbouring parts—Death.

A man was brought into the hospital on Tuesday, December 10th, at half-past four p.m. under the care of Mr. Brodie (it being his accident week). When admitted he was in a low and extreme state of collapse; tongue tremulous, and covered with a black furry coat; face and extremities cold, and endued with a clammy perspiration; pulse small, quick, and thrilling, and scarcely to be felt. On examination, it was discovered that he had an extensive foul black sloughy ulcer of the scrotum, penis and neighbouring parts, from which there had been considerable hæmorrhage. He was in such a low state of collapse, that no history of his case previous to his being brought to the hospital could be learnt, nor did the persons who brought him from Slaughter's Coffee-house appear to know any thing about him. He had been, we understood, in a declining state of health for some weeks previously, and had been under the care of some medical man, who must have most shamefully mismanaged him. Immediately on his admission he was put into a warm bed in Ratcliffe Ward, and wine, brandy, and other restoratives were given him.

Two hours after his admission his pulse could be more distinctly felt, his face and extremities, however, were still cold.

Dec. 11th. Died at half-past nine a.m.

He had, we understood, been subject to stricture of the urethra for eight years, and the medical practitioner under whose care he was placed, had done nothing for the slough but poultice it.

MIDDLESEX HOSPITAL.

Hemiplegia.

THE following cases of hemiplegia occurring in persons of a certain age, but not consequent upon apoplexy, will serve as an interesting chain of pathological facts to those already related in your excellent Journal. It will be observed that the principal features in these cases is the peculiar manner in which the disease arises. The individuals have, without any previous warning, found themselves all at once deprived of the use of one side of the body. The treatment adopted appears to have made but little way in improving the hemiplegic state, another interesting point in the pathology of the disease. This would lead us to the inquiry as to how far there was disorganisation of the structure of the brain, and the cause of such change if it existed. It does appear singular that the individuals alluded to should be struck powerless in one half the body, with their mental faculties unimpaired, and without the slightest warning of so serious a malady. I leave the subject here for the present, in the hopes that some of your correspondents may pursue this inquiry further.

John Walker, æt. 50, groom; brought to the Middlesex hospital under Dr. Wilson, January 1st.

Hemiplegia of the left side; the angle of the mouth is drawn to the right, and tongue pointing to the same; voice a little thick; a great want of expression in the features.

The sensation is perfect in the left arm and leg, but no motion; he complains of a pain, "like cramp," extending from the groin to the great toe of this side. These symptoms came on ten days ago. While talking to a friend he felt a slight numbness in the foot, which soon shot up to the face, extending along the whole left side of the body. He then felt a momentary giddiness, but never for an instant did he lose his senses. Pulse slow, laboured. He has been bled, his mouth is sore, and he has had a blister to the back of the neck.

Such active measures having been adopted, the physician thought it better to prescribe the most simple remedies, and according ordered the haust. gentianæ c. aloes of the hospital three times a day. This was changed subsequently for the haust. iodinii.

He continued this treatment, more or less, till April 6, when the following note was made.

Improvement very slow and gradual; the face is less distorted; the leg he can move a little, but the arm is of no use to him. The improvement being so tardy, he was ordered to be electrified, from this he experienced more decided benefit, and left the hospital considerably improved, April 30.

This and the following case are strongly illustrative of the important fact which Dr. Graves, with his usual ability, pointed out to his class, viz. that disease may commence in the circumferential parts of the nervous system, and so extend to the nervous centres.

James Elton, æt. 49, admitted under Dr. Wilson, April 6th; he has been always healthy; two or three mornings ago, while at breakfast, he felt "something in his left foot;" on endeavouring to raise himself from the chair he found he was unable, for he staggered and nearly fell down in the attempt; he then exclaimed, "I have lost the use of my left side." No headach, but after he found the side was powerless he felt a giddiness in his head which, however, did not for a moment suspend his mental faculties; he never had any fit; there is now complete hemiplegia of the left arm and leg; sensation not diminished, if any thing increased. He has been cupped, bled, and purged. He was ordered calomel gr. iij. bis die.

20th. No improvement; gums affected with calomel; iodine was administered in place of the former treatment, and this afforded some relief, as appears by the note of May 9th. He is able now slightly to move the leg in bed; his arm also, but not so much as the leg. He got up three times last week; upon

returning to bed he found the paralysed limbs much swollen; upon looking at them they presented the appearance of dropsical swelling, pitting on pressure. He is much altered in appearance, and looks older. There was nothing unusual in the further treatment, except that the dropsy was cured by the application of cabbage leaves as recommended by the French. Electricity was not employed in this case. The patient was discharged the latter end of June, much relieved, though not cured.

James Norman, æt. 47, admitted December 5th, under Dr. Watson, healthy in appearance.

Hemiplegia of the whole of the left side; sensation and temperature much diminished; the face is drawn to the right, and there is confusion in his speech. These symptoms were first observed yesterday, when he complained of a slight pain in the head; he took no heed of this, but upon rising from the chair upon which he was sitting, he found the left side powerless. V.S. ad $\frac{3}{4}$ iv., et c. c. nuchæ ad $\frac{3}{4}$ x., before admission.

Habeat calomel, gr. ij. 4tis et emp. lyttæ nuchæ.

14th. A little improvement; the leg improves faster than the arm; has continued the pills latterly twice a day.

Liniment, camphoræ co. Lin. ammoniæ, æq. part. brachio infricand.

25th. He is now able to walk pretty well; arm considerably improved; gums not affected.

Jan. 1st, Discharged much relieved.

He visited the hospital as an out-patient, and February 10th the following note was made.

The use of the paralysed side has returned, but when he walks he exhibits great weakness of that arm and leg. Some pain in the head at times.

He continues a patient of the hospital at the present time, Nov. 21st. He is electrified twice a week, and still complains of weakness and stiffness of the left side.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, December 12th.

John Cremer Bellamy	} Plymouth. Kingston-upon Hull.

CORRESPONDENTS.

Communications have been received from Mr. Radford, of Manchester, Mr. Pickford, of Brighton, M. Boudin, Dr. A. Thomson, Mr. Rush, of Paris, Mr. De Haume, of Glasgow, Dr. Corden Thompson, of Sheffield, Mr. Swift, of Dublin, a Middlesex Hospital Correspondent, and a Dublin Subscriber, all of which shall receive our earliest attention.

Dr. Thomson.—We are much obliged for the reports on French Medical Reform, as well as for various other communications forwarded by our indefatigable friend, and shall publish the former as soon as possible.

Mr. Pickford.—We shall publish the case at our earliest convenience.

A Dublin Subscriber.—We shall publish the valuable lectures of Dr. Stokes from this date, and in reply to this and several other correspondents, beg to state, that we had not received them earlier.

Mr. Porter's communication in our next.

* * We have to apologise to numerous correspondents for not having acknowledged their communications last week; but this arose from the confusion caused by the Editor removing his residence.

A Fellow of the Medical Society.—The strictures are unmerited, and much too severe.

A Philanthropist.—There certainly is no need of a second large hospital in the Borough, and while other parts of the metropolis stand very much in need of such an institution. There is a paragraph going the round of the newspapers, that the New St. Thomas's Hospital will, or ought to be, erected at Lambeth.

A St. Bartholomew Student.—Other schools are as badly off for subjects, and the fault lies with the parish authorities and not with the Inspector of Anatomy.

A London Hospital Student.—We must decline any comments on the collision of the medical officers of the institution. The matter will be publicly discussed in a few days.

A Member of the Westminster Medical Society.—Misconceptions are inevitable at all public meetings.

An Inquirer.—The North London Hospital is progressing rapidly, and it is expected to be open at the commencement of the next medical session.

A Stethoscopist's communication is in type but unavoidably postponed until our next.

A Subscriber.—We shall resume the translation of Baron Alibert's admirable work on Cutaneous Diseases, and have been waiting for the new edition, which has just reached us. We shall also give the lectures of MM. Dupuytren and Lesfranc at our convenience.

Dr. Ryan has removed to 4, Great Queen-street, St. James's Park, Westminster.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,**Session 1832—1833.*

LECTURE LXIX., DELIVERED MARCH 16, 1833.

GENTLEMEN,—In the latter part of the lecture yesterday evening, I explained to you that the venereal disease presents itself to us in a great variety of shapes, and is attended by apparently the most capricious irregularities, and this in relation both to the primary and the secondary symptoms: thus, we find, that some persons will have only superficial ulcers without induration around and below them, but with elevated or raised margins; while others will have sores, characterised by a hard circumference, an indurated base, an indisposition to granulate, and, in a word, all the features belonging to, what is called, the Hunterian chancre. Again, others will have phagedænic sores, entirely different from either of the other kinds now described; and while one individual will have only one sore of one of the descriptions here pointed out, another will have not merely a sore, corresponding to one of those varieties, but also a bubo; and a third will have gonorrhœa, in addition to the chancre and bubo. With respect to the secondary symptoms, these also exhibit the most perplexing diversities: the primary symptoms are frequently followed by secondary ones, as varied as the former, and even more so; thus, with regard to the cutaneous eruption, the spots on the skin may either be a scaly eruption, a papular eruption, a pustular eruption, or a tubercular eruption. The sore-throat also, which is a common secondary symptom, presents itself in a variety of forms: there may be a deep excavated ulcer on the tonsils, or only a superficial ulceration of them; or there may be an ulceration, extending to the upper part of the pharynx and soft palate, without affecting the tonsils. Then in the affections of the osseous

system, you may notice the same indisposition in the disease to confine itself to any determinate shape: there may be only periostitis, a mere swelling or inflammation of the periosteum, or there may be true nodes, or a real enlargement of the osseous texture itself—an increased deposition of bony matter; or there may be merely pains in the bones, or swellings and pains of the joints. Thus, gentlemen, you see in the outline of this singular disease, nothing but variety and irregularity, circumstances, which it is difficult to solve by reference to any principles, yet suggested by the many able men, who have exerted their talents in the investigation of this Protean disorder.

You know, gentlemen, that Mr. Carmichael attempted to explain some of the varieties of the venereal disease, by supposing a plurality of poisons; by the consideration that it is in truth not one, but several diseases, each depending on a specific poison of its own. His doctrine is, that, except in a few anomalous cases, every primary sore has its corresponding eruption; so that you may foretell by the appearance of the former what the latter will be, provided it come out at all; or if you see only the eruption, you may be able to pronounce from it what has been the character of the primary sore. If such progress had been made in the diagnosis of venereal complaints, we should have been in a very different position from what we found ourselves previously to Mr. Carmichael's doctrines; but, unfortunately, the conclusions to which his researches led him, are not confirmed by the general experience of the profession. When Mr. Carmichael's observations were first made known, they raised the most lively hopes, that a great step had been made in the knowledge of venereal complaints. But, the disease in London is not found to have the same regularity and constancy in the relations between its primary and secondary symptoms, as Mr. Carmichael thought that he had noticed in Dublin. As far as the evidence from other quarters can be depended upon, a primary sore of a determinate character will frequently communicate a sore of a different kind, and, what is still more inexplicable, frequently several sores,

each of different kinds. Certain facts, recorded by Mr. Evans, in an interesting work on venereal complaints, prove, that a connexion with a common prostitute, in whom there are no ulcers at all, will sometimes give rise to venereal complaints, and then the disease must have been communicated through the medium of the ordinary secretions of the genital organs, somewhat changed no doubt in their quality. As far as the doctrine of Mr. Carmichael goes, which ascribes the origin of phagedænic ulcers to a particular venereal poison, the idea does not seem to me at all tenable. We have seen that the phagedænic character may occur as a complication of any kind of ulcers, whatever may have been their original nature, and that such unfavourable change often depends on constitutional causes, bad health, injudicious treatment, intemperance, disturbance of the part, and other very definite and manifest circumstances. It is true, that we see in hospital gangrene and phagedænic diseases from syphilis, which are believed to be analogous to, or identical with, hospital gangrene, disorders certainly capable of propagation by contagion; but this refers to the accidental application of the matter, by means of sponge, &c., to the abraded surface, in another person. Without such abrasion there would have been no evil consequences. Then, how unlikely, how impossible I might say, it would be for a person afflicted with a phagedænic disease of the genitals to have sexual intercourse, so as to give the complaint to another person. On the contrary, we have reason to believe, that some of the worst forms of phagedænic ulcers are communicated by women, who have but trivial complaints themselves. No doubt, gentlemen, you have all heard of the captivating Lisbon opera-dancer, whose charms attracted so many of the officers of the British army into her embraces. If we are to credit the reports, many hundreds of our countrymen had connexion with her, no doubt civil also as well as military; and great numbers of them received, as a reward for their adoration of this irresistible goddess, the present of something more than a trifling clap. (*a laugh*). Many who had an acquaintance with this lady, I mean a very minute and close acquaintance with her, contracted venereal complaints of a particularly obstinate and afflicting kind, such as are comprised under what is sometimes facetiously denominated the *black lion*, (*a laugh*), a phagedænic, rapidly spreading, almost uncontrollable ulceration of the penis; yet it is curious to hear, that this lady continued to dance every night for months and months together, as if she were right in every respect herself, whilst her unfortunate friends were suffering all the pains and penalties inflicted upon them through the power of so fascinating a goddess, whose poison, like that of the serpent, hurt not herself. In truth, many of these devotees lost all they had (*laugher*) in consequence of these

exploits; I do not mean all their money, but something which no man would part with for any quantity of gold. (*a laugh*) Now it cannot be imagined, that she had phagedænic ulceration of the genitals, while she was discharging her duties so well, which consisted of dancing in the early part of the night, and of another sort of amusement in the latter part of it. (*laughter*) As far as I can judge, gentlemen, it is impossible to suppose that these phagedænic sores could have arisen from a particular kind of poison, the product of any phagedænic sore. Mr. Carmichael's description of the venereal disease is excellent, as far as the symptoms are concerned; we daily recognise in practice the very forms and shapes of the disorder which he has described so well; yet we see various circumstances, which prevent us from coming to his conclusions respecting the diversities of venereal diseases. We cannot trace any uniform and mutual correspondence between the primary and the secondary symptoms; the different effects, which he refers to different poisons, are found by us to be frequently too much blended together. One series of complaints is not so separate, so restricted to particular cases, as Mr. Carmichael's views would induce us to expect; for instance, we often meet with the scaly and pustular eruptions in the same patient. His account of the causes of phagedæna is totally incompatible with the facts revealed to us by experience. No doubt the Lisbon opera-dancer, I have alluded to, had not any thing very serious the matter with her; probably her natural secretions were somewhat changed, or she might have had at most some gleety affection. Then we must recollect another fact, which agrees with my inference from the opera-dancer's case; in the large towns in France, it is customary for the Cyprian corps to be inspected once a week by medical officers (*a laugh*); this was the established plan when I was abroad. Mr. Evans, who was stationed in Valenciennes, attended several of these interesting reviews, made under the direction of the police. The British garrison at Valenciennes, at that time, consisted of four or five thousand men, and many of them suffered severely from venereal complaints; there was at least the usual number of venereal cases among them: yet Mr. Evans informs us, that in the inspections referred to, where some hundreds of concubines were carefully examined, very little disease was found. Mr. Travers suggests one peculiar mode by which the venereal disease may be communicated; he supposes, that women may in some instances be the passive media of infection, that is, when a woman has had connexion with an infected person, and immediately afterwards has connexion with another man who is sound, the last person may be contaminated, though she may escape the disease. This seems possible; but whether it frequently happens or not, it is difficult to say. It seems as if the natural secretions of a female were some-

times more or less altered in their nature, though no ulceration exist on the surface of the genitals, and these changed secretions would appear to have the power in some instances of bringing on venereal complaints. I have already adverted to the opinion of my friend Mr. Travers, that if all venereal poison were absolutely to be annihilated at the present moment, we should have an abundant stock of it again in a short time; for he conceives that superficial ulcers on the glans penis, corona glandis, and prepuce, would lead to the production of the syphilitic virus, provided the subject, affected with them, were to have connexion with several women in succession; or that a man may have connexion with several women in succession who have only gonorrhœa, and elaborate in his own system the most virulent and concentrated form of the venereal disease, provided the inflammation affect the glans penis or prepuce, and such inflammation proceed to ulceration; but this is a theory on which I have not data enough to enable me to give any opinion worthy of being communicated to you. In certain respects it coincides with some of the views I have given you; but it may not accord with the general opinion. The mention of the term *concentrated* reminds me of another method of explaining some of the differences in the venereal disease, namely, by taking into the account the more or less diluted state of the virus; but this idea of the greater or lesser strength of the venereal virus is not universally received, nor does it agree with what is generally known respecting morbid animal poisons.

Gentlemen, I have already apprised you of the several important circumstances relating to the practice in venereal complaints: thus I have told you that syphilis is not invariably progressive from bad to worse, though mercury may not be employed: this is an important fact, worth recollecting in the treatment of the disease. Then I have informed you, that the venereal disease may generally be cured without mercury, and ultimately, even without any medicines whatsoever. Also, that mercury, so far from being a specific for this affection, sometimes aggravates its symptoms, and has the most fatal consequences. The old practitioners, implicitly confided in mercury as a specific for syphilis, and were blinded by the notion that it was the only means of cure; hence they sometimes gorged the system with it in such a degree, that every sanative process was rendered impossible. Then mercury, so far from making a favourable impression on the disease, ruined the constitution, and, operating as a poison, led to effects far worse than any which would have been the result of the disease left to take its course. If we recollect the tremendous havoc made in the human frame, arising from the practice, dictated by the notion that a cure of the venereal disease was impossible without mercury; and by the not less pernicious maxim of Boerhaave, *in dubiis suspice lœnem*; it may reasonably be

suspected, that the abuse of mercury has been productive of greater mischief, than the venereal disease itself, suffered to take its own course, would ever have occasioned. But this is not the fault of the medicine; but, of the manner in which it was employed, in consequence of the prejudices of the old practitioners, who fancied that, without mercury, the disease must progressively grow worse, and destroy the patient. Whatever was the state of the patient's health, in the commencement of the treatment, mercury was always pushed in every form of venereal complaints beyond all moderation, in quantities which no constitution could sustain without mischief. According to another idea, which is now exploded, every disease cured by other means, as for instance, by sarsaparilla, sudorifics, opium, nitric and sulphuric acids, and the nitro-muriatic bath, was pronounced to be not syphilitic, and this from the very circumstance, that it yielded without the aid of mercury.

Gentlemen, I wish you to understand, that mercury often facilitates the cure of venereal complaints; this is a truth, that seems unequivocally settled; yet generally speaking, the disease may also be brought to a conclusion without the influence of mercury. In this last sentence are contained the sum and substance of all the valuable inquiries made in modern times, respecting the absolute and essential necessity for the exhibition of mercury in the cure of venereal complaints. What I have here stated corresponds with the whole history of the venereal disease, and might have been seen long before the time of the late Mr. Rose, had practitioners not been completely blinded by assertions, delivered in the most dogmatical tone, by persons of the highest rank in the profession, who preferred to walk on in the old path, rather than make a new excursion.

But, gentlemen, the question about the necessity of using mercury in the treatment of the venereal disease, is not settled by our being told, that such medicine is not essentially and absolutely necessary for the cure. The decision for, or against its employment, must rest on other grounds; and first you should consider, not only whether the non-mercurial method is the most expeditious mode of cure, but whether it succeeds most effectually in removing the primary symptoms, and also in preventing, or curing the secondary ones? This view changes the question altogether. It has been fully proved, that you may cure all the primary and secondary symptoms of syphilis without mercury; but you are to inquire, is this the quickest way of doing it, and does this practice render the secondary symptoms less frequent? When you look over some of the evidence on these points, you might be induced to suppose, that mercury ought not to be given at all; but when the comparatively greater quickness of the cure of the primary eruptions, often exemplified when mercury is not given, is found to be counterbalanced by the comparatively greater fre-

x x 2

quency and severity of the secondary symptoms, when mercury is not given, our first impressions receive a check. On this point valuable and important documents are deposited in the Army Medical-Board Office; and you will find by those records, that out of 1940 cases of venereal primary sores cured without mercury, the average time required for the cure when buboes did not exist, was only twenty-one days; when there were buboes, forty-five days. On the other hand, when mercury was employed, out of 2827 chancres, treated with that medicine, the average time for a cure, when there was no bubo, was thirty-three days, and with a bubo fifty; so you see that here things are in favour of the non-mercurial treatment, as far as the primary symptoms are concerned, and without reference to secondary ones; and this corresponds with the results of similar investigations made in the Venereal Hospital at Paris, and which proved that the non-mercurial removed the primary symptoms sooner than the mercurial treatment. As far as you can judge from these official and authentic documents, it seems then, that the primary symptoms are in general more quickly cured without mercury than with it. But, as we are not compelled to restrict ourselves to either one method or the other, I think that the entire rejection of mercury, even in relation to the treatment of primary symptoms, (and abstractedly in this point of view,) is not rendered justifiable by any views, which have yet been brought before the public. This must be manifest, when it is acknowledged that a certain number of cases of primary symptoms, cured without mercury, (not perhaps a very considerable number) are very tedious ones; this is admitted by the strongest advocates for the non-mercurial treatment; perhaps, out of 2000 cases, twenty would be a very long time getting well. The calculations I have mentioned were the average of the whole number of cases, throwing out of view cases in which the cure was very tedious; therefore, with reference to them, a determination to abstain from mercury was, strictly speaking, decidedly wrong. The treatment of the primary symptoms of the disease should be diversified according to the judgment of the practitioner. A consideration, which ought to influence us more powerfully than the slowness or quickness of the cure of the primary symptoms, is the question, whether the secondary symptoms are more frequent after the non-mercurial than after the mercurial treatment. On this interesting point we receive different information from different quarters; one computation makes the proportion of cases, in which secondary symptoms followed the non-mercurial treatment, to be one in ten, while another statement makes it one in twenty; but the cases of secondary symptoms, where mercury had been given, were only one in fifty-five. This, then, is a most important fact, in favour of the use of mercury: its power in preventing the secondary symptoms from coming on, seems

to be greater than that of the other plans of treatment, or rather, I may say, that secondary symptoms more frequently come on when mercury is not used than when it is; but it does not follow from this, as a matter of course, that the way to have the smallest number of secondary symptoms, is always to give mercury; here you must use your judgment, and if, from the appearance of the sore, there is a likelihood that it will heal favourably, and it has not that decidedly venereal character, which Hunter and others dwell so much upon, then it may be better to wait and see what course the disease will take before the mercurial treatment is commenced. I believe, notwithstanding all that has been said, respecting the difficulty of recognising true syphilitic primary sores, that a surgeon, who is accustomed to the examination of venereal complaints, can generally discriminate them, at all events, from simple excoriations, boils, herpes preputii, and common sores; and that he will be able to recognise ulcers, which are more likely to be benefited by the use of mercury, than by other modes of treatment.

Whenever mercury is given, the wisest plan is to give it in moderation, and, above all things, to avoid the pernicious custom of putting the patient under a *course*, in which the mercury is given rapidly and profusely, and continued for an immoderate length of time. Experience has fully convinced me, that, in no variety of chancre, nor in any other stage of the venereal disease, is it proper to give mercury so unmercifully, and for so long a period as was formerly done. At all events, violent and long salivations should be given up. This practice, as I can state from my own observation in the foul wards of St. Bartholomew's Hospital, during a period of twelve years, instead of being more successful than the present methods, often led to the most dreadful of mutilations, and the number of those, who lost their palates and noses, was infinitely greater than what is now observed. I should guess, that for every such instance in the present day, there were then twenty. When you consider these facts, and couple them with the treatment which was employed thirty or forty years ago, you cannot avoid being brought to conclude, that a great deal of those ravages must have been produced, not by the disease itself, but by the manner of treating it. At present, the practice of subjecting patients to long and immoderate courses of mercury is given up by all experienced and judicious surgeons. Common ulcerations are also more carefully discriminated from venereal ones; and, when mercury is given, it is so administered as merely to produce a gentle affection of the gums and salivary glands, and not to occasion a total derangement of the whole economy.

Surgeons are now no longer blinded by the pernicious fear, that, unless mercury be given, the disease will continue to grow worse and worse till the patient is ultimately destroyed.

In former days, directly a patient was brought to a hospital, however bad his health might be at the time, it was immediately considered necessary to cram him with mercury. But we are now aware, that the notion, by which the old surgeons were terrified into such practice, was a mere ghost, nothing but a bugbear. When the patient's health is seriously impaired, I advise you, as a general rule, to postpone the employment of mercury till an amelioration in that respect has taken place. Even those practitioners, who place the greatest reliance on mercury as a specific, and still maintain that it ought to be called so, qualify their assertions by admitting, that it ought not to be given under every condition of the system; they candidly allow, that neither the condition of the parts, nor that of the constitution, is at all times such as will let mercury be given with impunity; they confess, that its rash and unscientific employment will aggravate the symptoms; and they specify two cases, in which its use is generally erroneous, namely, during excessive weakness of the system, and while the disease is complicated with excessive inflammation. Under these two conditions, the greatest advocates of mercury commonly admit, that its employment should be postponed. But these are not the only states, in which it should usually be prohibited; it should not be given during any great derangement of the system from diarrhoea, or fever, or from what is termed *erythismus*, a peculiar state of constitution, in which the patient labours under excessive irritability, weakness, palpitation of the heart, and other evils from the mercury already given. There are some constitutions, in which this condition is liable also to be induced by a very slight quantity of mercury, and when it is present, the patient may die suddenly on making any trivial exertion.

Gentlemen, the next part of the subject will be the consideration of the different preparations of mercury, but, as the evening is advanced, I will let this topic stand over till Monday.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XII.

Artificial Lactation.—Dry Nursing.—Solid Food of Infants.—Ab lactation, or weaning.

GENTLEMEN,—When circumstances will not permit of the employment of a wet nurse, the infant ought to be nourished with the milk of some of the inferior animals. Every kind of milk varies, at different times, in its physical and chemical properties. A woman does not supply the same kind of milk at different hours of the day, and no two individuals afford a

fluid of the same quality. It is therefore fairly inferred, that a wet nurse is but a bad substitute for a parent; and that every mother of a sound constitution is bound to suckle her infant. Lactation is but a part of re-production, and is considered as important as generation itself, and even more so by some writers:—

“Quæ lactat mater, magis quam quæ genuit”

Milk is, in general, an opaque, white, mild fluid, containing water, sugar, cheese, and butter. These substances are in different proportions, according to the species of animal which supplies the milk, and hold in solution different salts, the earthy phosphates, and the hydrochlorates of potass and lime. Besides these constituents, which are found in the milk of the woman, the cow, the sheep, the goat, the ass, and the mare, there is a difference of taste and aroma. The aroma is dissipated in a short time if the milk has been exposed to the air, a fact which was first noticed by Galen, and more especially by the effect of ebullition or boiling.

There are usually six animals, whose milk is employed as an aliment by mankind, and these may be divided into two classes. In the first are included ruminating animals, as the goat, sheep, and cow, in the milk of which the caseous and butyraceous parts predominate, the sugar and serum are in less proportions. In the second, which comprises the milk of two herbivorous animals, the mare and the ass, and that of the woman, which approaches both in some respects, the sugar and serum predominate over the butyraceous and caseous substances. According to the numerous researches and experiments of MM. Deyeux and Parmentier, and Dr. Young, the physical and chemical properties of milk vary every instant; they observed, on examining three portions of the same milk at different times, the first contained more serum, the second more cream, and the third more butter and cheese.

This observation is equally applicable to the milk of women, and is extremely important as regards the manner of suckling infants, because when the breast is presented too often the milk will be too thin and serous, while it will be much richer when allowed to accumulate for some hours, as time will be allowed for the more fluid parts to be absorbed.

Every one knows that the quality and quantity of milk will be modified by the food of the animal. Again, the odour and taste of the aliment will be imparted to the milk. This fact is exemplified by the milk of the cow, sheep, goat, &c. It is also well known to medical practitioners, that aliment and medicine, taken by a wet nurse, will affect the infant. We often see examples in attestation of this fact. A nurse takes an aperient, and the infant is affected by it; we exhibit mercury to the former, and it cures the latter, when infected with syphilis. These facts are to be borne in mind by those engaged in the practice of medicine. They are daily proved in

hospitals, dispensaries, and private practice. The secretion of milk is modified by all acute and chronic diseases. In acute diseases it is often suppressed, or very much diminished; but it is much less affected in chronic complaints. MM. Deyeux and Parmentier examined the milk of a woman after a severe nervous disorder, and found it transparent, viscid as the white of an egg, and in some hours afterwards it assumed its ordinary character. The moral causes have as much influence as the physical, on the human milk. All the passions injure this secretion. They sometimes suppress it suddenly, or render it so hurtful to the infant, as to cause colic, griping, or convulsions. Drunkenness produces the same effects. Boerhaave relates the case of a child, who was seized with convulsions, after having sucked the breast of a woman in a state of intoxication. How deplorable it is, then, to behold the crowds of the lower classes entering spirit and gin shops with their infants in their arms; and it is a well known fact, that these unfortunate little creatures are compelled to drink the same deleterious beverages as their intemperate and wretched parents. It is also a popular custom to mix ardent liquors with infants' food, for the purpose of inducing sleep and allaying pain. The exhibition of fermented liquors, such as wine, porter, ale, &c., is somewhat less condemnable, but even these are highly improper and injurious. The delicacy and irritability of infants, together with their predisposition to gastric irritation, render them extremely liable to numerous diseases, and these are rapidly excited by the ingestion of spirituous and fermented liquors, and by their influence on the milk of nurses. The delicacy and susceptibility of the nervous system of the other sex, predispose them to the same consequences. Hence we observe them nervous, hysterical, and dyspeptic. Every kind of liquor is greatly adulterated in this country, as I have proved in my Manual of Medical Jurisprudence; one with narcotics, another with acrid spices. The spirituous liquors cause furious ebriety, while the malt liquors induce stupor. Hogarth has well illustrated drunkenness caused by beer, and that induced by ardent spirits, in his caricatures entitled *Gin Lane* and *Ale Alley*.

The bad effects of intoxication on the constitution are an access of fever with an exaltation of the vital and intellectual powers, followed by delirium or coma, and terminated by a copious discharge of urine, or by profuse perspiration, by sleep, sometimes by vomiting or diarrhoea, and finally by apoplexy, convulsions, partial paralysis or palsy, or by a peculiar derangement of the mind, accompanied by tremblings of the body, which is denominated delirium tremens vel ebriosum, vel à potu, a malady most graphically described by my experienced friend, Dr. Blake, now of Nottingham.

But the immediate consequence of drunkenness is indigestion, modified by the kind of

drink, according as it has been excitant, narcotic, acid, in a state of imperfect fermentation, or falsified by various adulterations. The most frequent disease caused by inebriation from the excessive use of ale or porter, is apoplexy. The nutritive parts of these beverages induce obesity or corpulence, which impedes the circulation of the blood, and accumulates it in, or determines it to, the head. Stimulating or excitant potations, as ardent spirits, act on the brain and spinal marrow; or, to speak scientifically, on the cerebro-spinal system. It is not unusual at the point of inebriation, before stupor supervenes, to see an attack of convulsions, epilepsy, or hysteria. In other cases we observe tremblings of the limbs, headache, loss of appetite, furred tongue, flatulence, extreme lowness of spirits, nervous delirium, and partial or general paralysis. The mental and corporeal powers are greatly depressed by intoxication. The attention, memory, judgment, and imagination are impaired, and finally destroyed. The mental and corporeal excitement, is followed by proportionate depression or collapse. The drunkard becomes careless and slovenly in his dress, irresolute and timid in all his affairs, and ultimately he is remarkable for brutishness and stupor, and he usually dies of apoplexy, paralysis, asthma, dropsy, disease of the liver, spleen, stomach, bowels, or genito-urinary organs. He is also liable to diseases of the lungs, heart, and skin. Among the cutaneous eruptions, we must not forget the florid colour of the nose, so forcibly and grotesquely described by Shakspeare in his description of Bardolph,

"I never see thy face, but I think of hell-fire." nor the ulcers, boils, and pimples on every part of the body. These are not all the diseases caused by ebriety,—we must not forget melancholy and mental alienation. The inference, therefore, which is obviously deducible from the preceding statements is, that intemperance is highly injurious to health, and must be extremely dangerous to wet nurses. But a moderate use of wines, spirituous, and malt liquors is essential to health. Panegyrist of wine have left us, among many others, the following adage, which applies to all liquors:—

"Si nocturna tibi noceat potatio vini,
Horà matutinà rebibas, erit medicina."

I should not have introduced the preceding remarks, were it not that the majority of the lower classes of suckling women in all countries, are in the habit of taking strong liquors too freely.

All excitants or depriments of mind or body are injurious to suckling women, as excess of pleasure, of sadness, grief, &c. In proof of this opinion, it is sufficient for us to observe the languishing state of young infants, nourished by women who enjoy the pleasures of society, at the expense of sacrificing the duties of maternity. Civilisation estranges the rights prescribed by nature. Hence we find unnatural or mercenary lactation very differen

from what nature intended in all large or crowded cities.

Milk is the aliment of young infants in almost all countries, and it is supplied by the mother, another woman, or an animal. The mother's milk is the best for her offspring, provided she is of a sound constitution. The milk of the rein-deer in Lapland, of the mare in Tartary, of the dromedary, the chamois, or wild goat, in Egypt and Syria, the buffalo in the West Indies, the lama, or Peruvian sheep in South America, and, finally, the cow, the sheep, the goat, and the ass in the temperate climates of both continents, but especially in Europe, supply mankind with an abundance of milk, for a simple and nutritious aliment.

But the milk of the cow is most employed, either alone or without any decomposition, or when its component parts have been separated spontaneously, or by art. It is an aliment more nutritious and animalised than vegetable food, and is easily acted on by the stomach. It disagrees, however, with infants when their digestion is good; and some do not consider it sufficiently invigorating for those, whose lymphatic system predominates, and who are predisposed to scrofula. It has also been proved that the milk of woman, or of the cow, is much more acid at one time than at another, and may disorder the stomach of infants. Milk is not a proper aliment for all persons; it would be insufficient for strong men, who pursue very laborious employments, and who necessarily require the strongest and most animalised aliments. Some persons do not digest it well, unless mixed with other foods, as tea, coffee, puddings, pastry, &c. It is most fit for the young and aged, whose powers of digestion are moderate. When it forms the only article of diet, as in cases of infants, it often causes hiccup, vomiting, diarrhoea, depraved motions, curdled and of various colours; and in the adult, when used exclusively or too freely, it induces fulness and pain in the stomach and bowels, heartburn, water-brash, flatulence, &c., &c. When it disorders the stomach and bowels of infants, we usually exhibit magnesia or prepared chalk, and add a sixth part of hot water, with a small portion of loaf or purified sugar to it. The Divine Author of Nature, as in all his works, admirably designed a remedy for this evil. He has most wisely ordained, that innumerable circumstances modify the milk of woman and other mammiferous animals, every moment in the day; and that a fluid possessing the same physical and chemical properties, is not afforded from even the same source.

In general milk agrees with infants, but when mixed with farinaceous food, as bread, gruel, arrow-root, &c., it often disorders the stomach by irritating it; the effect of which will be, an increased secretion of an acid or imperfect gastric fluid, which coagulates or curdles the milk, renders it indigestible, and the consequences will be, hiccup, griping, and sometimes convulsions. M. Gardien is of

opinion that cow's milk boiled with bread, or other farinaceous aliments, is more easily digested than when either is taken alone. He says, the cheese and the gluten form a chemical combination more easily digested than either, and that children like this food when milk disagrees with them.—*Dict. des Scien. Méd.*, art Nourrice. But we know, that few adults could live on a milk diet only; and that indigestion is very speedily induced. Nevertheless a milk diet is highly beneficial during convalescence, and in an immense number of diseases. It has been administered since the time of the father of medicine. Hippocrates used it diluted with water, in acute and chronic diseases, and in epidemics. Aretæus strongly recommends this fluid, under the name of hydrogale, composed of two parts of milk and one of water, in phthisis dorsalis, elephantiasis, and many other disorders. Sydenham and Heister employed it as a drink in small-pox; and others considered it too nutritious during the state of excitement in continued fevers, and therefore used whey. The late revered Dr. Armstrong recommended wine and milk in the state of collapse, and I have often tried it in this combination with advantage. Hoffman, Vogel, and others, advised it as the vehicle for mineral waters, and with great benefit. It has been given in consumption and many other chronic diseases. As an article of diet, we find milk employed alone or combined with water, ardent spirits, in small quantities, and even with beer. Mr. Cameron contends, in his work on Diet, lately published, that if milk were more generally employed there would be much less disease. The comparative qualities of milk deserve attention. That of the cow is most generally employed as food, and in therapeutics, it exceeds that of all other species in sugar of milk and in serum, it is therefore lighter, but invalids often find it indigestible, and in such instances we prefer the milk of the ass, though formerly, that of woman was considered and is unquestionably the most nutritious.

The milk of the goat contains more cheesy matter and less butter than that of the cow or sheep. Its aroma is much stronger, as the animal that supplies it browses on more aromatic herbs than either of the others. It is more tonic or strengthening, and slightly astringent, and is extremely valuable to those enfeebled by disease, and to infants who are naturally weak. It agrees with some individuals who cannot bear any other kind of milk. It is apt to cause want of sleep, and render infants too vivacious. That of the sheep contains most butter, and least sugar or serum.

The human milk is richest in sugar of all kinds already noticed, and was formerly recommended in the cure of diseases. That of the ass approaches nearest to it, and hence this is so strongly recommended for delicate infants and consumptive individuals. The milk of the mare closely resembles that of the woman and the ass, but is so seldom employed

that its nutritive qualities cannot be justly estimated.

The milk of carnivorous animals is not used as an article of diet or in medicine.

Though the milk of the cow contains more butter than that of the woman, the ass, the goat, or the mare, custom has caused it to be preferred, when breast milk cannot be obtained. But it is too rich for the infant, and must be diluted with a sixth part of warm water, whey made without acid, or barley water, and a small quantity of pure sugar should be added. This dilution should be continued, though it may be gradually diminished every day until the sixth month, when the infant can generally take milk without any mixture. It should be procured warm from the cow, and given to the infant; as in this form it possesses its aroma, which evaporates when the milk is exposed to the air or is heated over the fire. The practice of boiling milk, and reheating it several times, renders it most injurious to infants. Few adults could continue it after such a process without having their digestion greatly deranged. When milk is boiled, it is deprived of its aroma, rendered more difficult of digestion, and astringent. Here I am compelled to differ from Dr. Underwood, who holds "that the milk ought to be boiled if the child is very young, or has a purging." And again, "at first the milk ought to be boiled to render it less opening; but when the child is several months old, or may chance to be costive, the milk need only be warmed." It appears to me, that the addition of a fourth or sixth part of warm water to the milk, with a small portion of loaf, and not Lisbon sugar, is the better mode of preparing this food for infants. A small teacupful will be sufficient for each repast, as the stomach of a new born infant is not capable of containing a greater quantity of fluid than about three tablespoonfuls, or a small wine-glassful. The milk should be as new as possible, and if warm from the cow so much the better. The quantity for each repast should be prepared at the end of every two hours, as in general an infant cries or awakes from its sleep about this period for the purpose taking aliment.

It is utterly impossible to lay down a rule as to the exact quantity of food, or the frequency of giving it to infants, as this must depend on their development, health, vigour, or delicacy of constitution, and on the quality of the milk. Even when the infant is nourished with breast milk, it will be necessary, after the first month of its age, to give it cow's milk prepared as just stated, more especially if the mother is delicate; but the addition of farinaceous substances, as bread, gruel, &c., is improper and injurious, and what nature has not intended. It is also important to describe the manner the infant should be fed with cow's milk. This should be poured into a sucking bottle, on the mouth of which a piece of wash leather, vellum, parchment, or sponge is properly secured, so as to represent the nipple. This contrivance

obliges the infant to take the milk by suction which increases the salivary secretion, the mixture of which with the food facilitates digestion. This method is preferable to making the infant swallow milk from a boat, pot, horn, or spoon. The bottle with a prepared teat is also a good contrivance. The bottle should be washed before each repast. Some writers recommend one part of fresh cream diluted with four or six parts of water, and sweetened with a little sugar, as the best substitute for the maternal milk, which at first is chiefly composed of cream and water. The superiority of cream over milk arises from its being destitute of curd, which an infant cannot digest. It is necessary to add but a very small quantity of sugar, as otherwise the digestive function will be deranged.

Milk alone is the proper food for healthful infants until the teeth appear. It often happens that the infant will pine on the use of all other aliments. These facts evidently show the impropriety of the various foods which are usually administered to infants. The errors committed in the diet of infants are in a great measure to be attributed to Underwood and his disciples, who advise thick food after the first four or five months. I fully assent to the opinion of Ratieur and other able writers, that broths, soups, gruel, various vegetable jellies, arrow-root, patent barley, salep, bread, animal food, ought to be proscribed during the time that nature destined for lactation. "If you wish," says Ratieur energetically, "to deprive your infant of the aliment which was destined for it by Providence, if you have not the courage to nourish it, at least do not poison it." On the other hand, we find Dr. Hugh Smith recommending milk to be mixed with thin gruel, or barley-water, as the food for new-born infants, and Underwood reiterating the advice; the latter held that after a few weeks, the jellies of hartshorn, arrow-root, tapioca, sago, &c. should be given; and after four or five months, a French roll boiled in water to a jelly, and mixed with milk, and also thick food, were requisite. About this age he considered beef-tea, broth, or gravy without fat, and diluted with water, light puddings made of bread, tapioca, semolina, rice, arrow-root, salep with milk, as proper aliments for infants. These are highly useful, when there is not a sufficient supply of milk, or when the infant is ricketty; but are not necessary when the nurse and her offspring are healthful.

The eruption of the teeth is the signal for the change of the infant's diet. The articles enumerated in the last paragraph are now proper. Primrose has well observed, that animal food is improper, however well minced, until the teeth are formed. This food cannot be digested by the weak stomach of an infant, it passes into the intestines in a crude state, and then produces irritation, inflammation, or ulceration, giving rise to infantile remittent fever, worm fever, tooth fever, to diarrhoea, or enlarged mesenteric glands. The exhibition of

animal food to toothless children is a common practice among women, and a fertile source of infantile diseases. We daily observe the bad effects of this custom among dispensary, and indeed private patients. Mothers will inform you, that they give their children the same food as their family.

There is no doubt but children have a great desire for animal food, and they may be gratified according to the plan proposed by Dr. Hugh Smith, even so early as the third month. "The gravy of beef or mutton, not over roasted, and without fat, properly diluted with water, is the most wholesome and most natural, as well as the most nourishing broth that can be made." This or beef-tea, or chicken-broth may be mixed with bread, mealy potato, or arrow-root, and will form an excellent aliment, as it requires no mastication. I have advised this diet, in numerous cases, with the best effects. Nevertheless I agree with Primrose and others in the opinion, "*ante dentium eruptionem non conveniunt cibi solidiores. Ideo natura, quæ nilfr frustra fecit, et non deficit in necessariis, dentes ipsi denegavit, sed lac concessit, quod masticatione non eget.*" Some writers have gone so far as to prohibit this aliment until children were four years of age, and even then they should be cautioned to chew it well.

As soon as the teeth appear, a new regimen becomes necessary. At this period a crust of bread may be given to amuse and nourish the infant; and many consider this the best "gum-stick." A little later, pure milk may be given with farinaceous substances, such as bread, sago, arrow-root, salep, rice, biscuit, and farinaceous powders; prepared barley, the fecula or substance of dry mealy potato mixed with milk, or gravies, soups, broths, beef or chicken tea. Flesh meat in a solid form, as chicken, veal, &c., must be withheld. It is worthy of remark, that the illustrious Locke, and others, thought that strong food, and such as was difficult of digestion, ought to be given to exert and strengthen the stomach.

There is a precept to be observed on diet from infancy to puberty, which is, to give but a moderate quantity of food at each repast, and never to refuse it when required. The usual error is giving too much.

From the earliest age the infant should be fed in the sitting posture, and not on the back, as it will swallow much better, and with much less danger of the food impeding respiration, or of exciting coughing. This advice is contrary to long established usage; but, were it questioned, it would be easily established, by referring to the difficulty an adult would experience in taking food on the back, or in the recumbent position.

It is a bad custom to induce children to eat by placing sweets and other enticing aliments before them, as they are naturally voracious, and take too much, unless restrained. The rapid growth of the body requires a frequent supply of nutriment; and hence the child re-

quires food at short intervals. Hippocrates well observed this fact:—"Senes facillime jejuniū ferent: minimum adolescentes, omnium vero minime pueri; atque inter ipsos qui alacriores sunt." "Infancy and childhood," says Arbuthnot, "demand thin copious nourishing aliment." It is extremely injurious to their growth and health to compel them to remain hungry until the time at which their parents take their repasts; and it is equally improper to suffer them to partake of these. Children should not be allowed at table with adults. As they are all gluttons and take too much aliment, it is necessary to pay proper attention to the regularity of the bowels. We cannot lay down a better rule on this head than that of the illustrious Locke,—to present the child to the chamber utensil every day at the same hour until the habit is established.

Milk and water form the best drink for children; and they should never taste any kind of liquor unless ordered as a medicine. It is lamentable to reflect on the baneful practice of exhibiting gin, porter, ale, wine, punch, cider, &c., to infants, which is an every day occurrence among the working class of society. These liquors are given pure, or mixed with food, and cause the destruction of thousands of human beings. The young of the human species only are subjected to this horrible treatment; those of all other animals are exempt from it. Tea, coffee, cocoa, and chocolate, are also improper for infants; milk alone can be given with safety and advantage. While adopting this plan, the mother should accustom the infant to foods described in this article. It is scarcely necessary to observe, that all high seasoned, salted, smoked foods, pastry, sweet-meats, and fruits, are highly injurious to children. When the child is ill, from whatever cause, whether fever or inflammation, it will refuse every kind of food, and subsist for several days on cold drink, barley-water, milk and water, tea, toast and water, thin arrow-root, sago, or tapioca. Should it labour under severe bowel complaint, boiled milk, or what is termed rice milk, will often afford relief. In this case, as there is seldom any fever, beef tea, chicken broth, calves' foot and other animal jellies, will be required to support the strength. In such instances, the use of spiced or spirituous liquors, as mulled Tent wine, gin, port wine, &c., are improper, and should be prescribed by proper medical authority only.

The proper time for weaning will vary according to the constitution of the mother and of the infant, and the early or late appearance of the teeth. It is impossible to establish any general rule as to the age at which an infant should be deprived of the breast milk, for all are not fit to be weaned at the same time.

In general, lactation or suckling may be continued for nine or twelve months: it may be discontinued, when the infant is strong, plump, and vigorous, at the eighth; but it must be prolonged when the infant is feeble

and delicate, and when the teeth appear slowly, as in rickety children.

When the child is strong and healthful, it may be weaned after the first twenty teeth appear, which is from the sixth to the ninth month; but when weak, feeble, and unable to walk, it should be suckled for fifteen, eighteen, twenty, or thirty months, provided the milk is abundant and good.

Buffon informs us, that "in Italy, Holland, Turkey, and through the whole Levant, children are rarely allowed any other food than the breast milk during the first year;" and the savages in Canada suckle for four or five, and sometimes for six or seven years. Some practitioners think on the contrary, that prolonged lactation injures the mother, and induces scrofula, rickets, hydrocephalus, &c., in the infant; but the profession in general maintain, that it is wisest to continue lactation as long as possible, or, in other words, to be guided by the principles already stated. Astruc advised children to be suckled until they were two years old. In general, women become pregnant at the end of twelve months, and this, when it occurs, would indicate the proper age for ab lactation.

It is highly detrimental to a healthful child to be allowed the breast milk after a year; because it weakens the mother, injures the breast milk, and becomes liable to diseases.

It would be injurious to commence weaning before or during dentition, or when the child was unwell. The diet, mentioned under the head of Solid Food of Infants, should be given for some time before the infant is deprived of the food with which nature supplies it. This is the more necessary, because sudden weaning is followed by numerous diseases. When ab lactation or weaning is effected too suddenly it is injurious to both parent and offspring. Dr. Underwood strongly recommends immediate weaning, and putting the infant, without any preparation, upon common food. He says he almost lived in the nursery, for many years, and never saw any bad effect from the sudden transition. Reason and physiology are, I feel convinced, against him. Lactation should be progressively diminished, until the infant would suck only once a-day, and finally, once in two or three days.

Dr. Underwood observes, that "every kind of food, and even drink, should be prohibited in the night, even from the first, supposing them to be weaned at a proper age. The mere giving them drink, even only for a few nights, creates the pain and trouble of two weanings instead of one; and if it be continued much longer, it not only breaks the rest, but the child will acquire the habit of drinking; the consequence of which very often is a large belly, weak bowels, general debility, lax joints, and all the symptoms of rickets. The only need is, that the last feeding be just before the nurse goes to bed, which may generally be done without waking it; and whilst the child seems to enjoy this sleepy

meal, it becomes a most pleasant employment to the mother, or nurse, from observing how greedily the child takes its food, and how satisfied it will lie for many hours on the strength of this meal." In the meantime it should be nourished with the solid aliments formerly described. When the breast milk is abundant, the mother or nurse should diminish the quantity of her food, and especially of drink, have her breasts drawn once a day, and apply a lotion composed of one part of vinegar and six of water. Her bowels should be relaxed by castor oil, or some other mild aperient.

Though I respect the opinions of this writer in general, I must dissent from his doctrine on this head; because the child will require drink once at least during the night; and unless its want be supplied, it will awake, disturb the parent, and injure itself by long-continued fretfulness or screaming. If it sleep soundly, which seldom happens, then it should not be disturbed.

FRENCH MEDICAL REFORM.

REPORT OF A COMMITTEE OF THE ACADEMY OF MEDICINE AT PARIS UPON A PLAN FOR A RE-ORGANISATION OF MEDICINE IN FRANCE.

READ BY M. DOUBLE,

*To the Academy, at the Sitting of the 22nd
October, 1833. Translated from the Gazette
Medicale*

BY ALEXANDER THOMSON, M.B., OF ST. JOHN'S
COLLEGE, CAMBRIDGE.

TOWARDS the end of 1829, said the honourable reporter, the Minister of the Interior addressed to the Academy a series of questions, relative to the re-organisation of medicine. A commission was named to examine them, and immediately commenced its labours. But the presiding idea of the plan of the government of that period, to which it seemed to adhere irrevocably, of submitting medical men to councils of discipline, into which the *prefets* and the *procureurs du roi* should enter as a matter of right, was calculated, from the very first, to throw discouragement into the labours of the commission; it proceeded, therefore, but slowly. The revolution of 1830 interrupted the course of its researches, and the epidemic cholera, which lately absorbed all the attention of medical men, had contributed to make them altogether forgotten; when, by a letter of the 30th July last, Monsieur the Minister of Public Instruction, recalled this object to the notice of the Academy, and claimed its so long suspended answer.

The former commission found itself re-constituted, and has examined the matters submitted to it with all the care they deserve. It has devoted twenty-nine sittings to the discussion; it has sought to surround itself with every light, to examine maturely every argu

ment, for and against; it has considered itself in this position as the advance guard of the medical body, and that it was combating *pro aris et focis*. It is satisfactory to be able to state in the commencement, that upon each of the points, on which it has had to deliberate, its decisions have been arrived at unanimously.

From the commencement of the Revolution, the different successive governments have sought to enable medicine to participate in the ameliorations spread through the whole social body. Among the works published upon this subject, the first in point of date, and still more the first from its importance, is that which was addressed in 1790, by the Royal Society of Medicine to the Constituent Assembly. A second report was made in 1791 by M. Talleyrand Perigord. In 1792 a new plan was brought to light, the most remarkable perhaps for the connexion of theoretical views, unhappily also the least rich in truly applicable practical consequences. The Convention even found time to occupy itself with medical institutions, and caused the *Ecole de Médecine* to be re-opened; and since that period the Council of Five Hundred, the Consulate, and the Empire have renewed, modified, and increased the mass of laws and of regulations relative to our profession.

It is not in our days only that governments have felt the importance of adding to the lustre of medical institutions. From the commencement of the University of France, medicine was comprised in it; at a later period it constituted one of its four faculties, and since the edict of the 1st of June, 1452, the first code of medical institutions in France, there has scarcely been an attempt to give regularity to public instruction, without extending similar views to medicine.

Surrounded with all these relics of an age already ancient, and of an epoch quite recent, the commission has deemed it its duty to receive them, not as authorities, but as simple documents, disposed to consult, but at the same time to examine, every thing carefully, and regarding the past not as a rule but as a result of experience, useful to be known for the future. Its task did not however extend to trace a complete and universal plan of Medical Reform; charged only with answering certain questions precisely stated, it has been obliged to accept its mission, such as is presented to it, and to restrain itself within the limits imposed upon it.

A fact of immense importance, a fact inprescriptible and irrefragable, has presided over all its labours, namely, the liberty of teaching, guaranteed by the charter of 1830. The sixty-ninth article states, in formal terms, "There shall be provision made successively, by separate laws, and within the shortest possible delay . . . for public instruction, and for the liberty of teaching." Demanded especially by medical men, the liberty of teaching presents itself to them with all its advantages, and deprived of all its inconveniences; the in-

struction resulting from it is profitable both to those receiving it and to all citizens, to whom it furnishes further guarantees. In fact, so many reasons militate in its favour, that the commission does not hesitate to declare boldly, that "the monopoly of teaching becomes particularly absurd in medicine."

The following is, in the commencement, a summary of the questions agitated and resolved in the report:—

"The questions of the officers of health (*officiers de santé*) deserve to be treated the first; the commission has been led to demand the suppression of this institution, as well as of the medical juries, and of their official trips in the departments.

"It has thought to endow medicine with a new and powerful safeguard, by the creation of medical councils of departments, which will be a means of re-union and of action to the isolated medical men of the provinces.

"It will call for the complete suppression of secret remedies, properly so called, hitherto the incurable wound of medicine. Enlightened by profound historical researches, it hopes to indicate the means of curing, by satisfying at once the interest of the public and of individuals.

"In a very extensive chapter, which will be composed of numerous articles, it will pursue all the abuses which have glided into the teaching and practice of the healing art, taking care to indicate, by the side of the evil, the means of remedying it. To give an idea of the importance of the questions, which will be treated in this branch, the honourable reporter cited, by way of example, the admission of foreign medical men to the liberty and practising of medicine in France; the prosecution of offences against the law; medical responsibility; licences (*patentes*), &c.

"Finally, the commission will terminate its labours by seeking out the abuses which have crept into the practice of pharmacy. It will demand, that the preparation, the composition, and the sale of medicines be reserved exclusively to the pharmacians (*apothecaries*); that pharmacy be precisely and absolutely isolated from the sale of drugs, and from other professions, which every day attempt to encroach upon it; and the question of the utility or of the necessity of a pharmacopœia (*codex*) will find its place."

After having given this summary of the labours of the commission, let us enter directly upon the subject.

In the first rank, as has been said, is placed the question of the *officiers de santé*. It has appeared to the commission to be of more importance than all the others, and upon the solution of this capital and decisive point depends the whole new medical organisation.

The question put by the government is thus expressed:—

"Can we, without inconvenience, renounce having two orders of medical men?"

To answer it deliberately, let us see first

what existed formerly in France, compared with what exists in the present day, and contrasted with the medical institutions of neighbouring nations.

Preliminary studies, long and solid, a diploma, required in the Faculty of Letters, and recently even another diploma, required in the Faculty of Sciences; four years' inscriptions taken in a Faculty; five examinations, crowned by an inaugural thesis; expenses, which, for the University rights and the diploma, amount to 1,100 francs (about fifty pounds sterling). Such are the obligations that must actually be fulfilled by the Doctors in Medicine, or in Surgery.

Preliminary studies, none or insignificant, three years' study in a Faculty, or in a secondary school, which may be replaced by six years' presence in an hospital, or studies with a doctor; three examinations, most frequently illusory; an outlay amounting, for the University rights and the diploma, to 250, or at most 300 francs (about ten or twelve pounds sterling), there is what is required from the *officiers de santé* (a species of general practitioners).

To the first is reserved the right of practising to the fullest extent throughout the kingdom. The rights of the second have been in some respects limited, but the restrictions have been constantly illusory: the Doctors of Medicine recoiling before the anxiety and scandal of enforcing their rights by law-suits, and even the tribunals hesitating to apply the law in all its rigour.

Before the decree of 18th August, 1792, ordering the suppression of the Universities, and of the degrees conferred in them, there were in France two classes of practitioners, who corresponded tolerably closely to the present organisation; 1st. Doctors admitted by the Faculties and Masters of Surgery, corresponding to the Doctors in Medicine; 2ndly. surgeons admitted by the lieutenants of the first surgeon to the king, and who may be compared to our *officiers de santé*. It is, however, just to admit, that the latter are generally better instructed than were the surgeons and barbers of the lower orders; but this increase of instruction is not peculiar to medicine, it is found equally in all professions.

Let us now consider what takes place in neighbouring nations. In England the apothecaries have the right of practising and of prescribing the remedies they prepare; they, in truth, form a class of practitioners inferior to the physicians.

In Prussia, Germany, and Italy the physicians and surgeons are admitted separately; but every where, as formerly with us, with the exception of some of the heads elevated to the first rank by their talent, the surgeons in general, and even some of the medical men, compose the inferior class, and serve most commonly as assistants and servitors to the others.

Thus, in this general review, we meet every

where with two orders of practitioners. Must we conclude that such a state of things ought to be our guide, and that the past ought to form in this case a law for the future? Quite the contrary: since this past no longer corresponds to the irresistible wants of a new state of society; since, on all hands, there arises an unanimous outcry, it is too evident, that we must seek, in this organisation itself, for the cause of this restlessness which torments us; and that the errors of the past ought to serve us as lessons. Called upon especially to correct the defects of the ancient legislation, the new legislation must, before every thing, prove its superiority to the other; it is only by deviating from the route hitherto followed that we can act otherwise and better.

And first, this idea of creating by a law two orders of medical men unequal in rights, in instruction, in capacities, is manifestly repugnant to reason and to justice. Humanity even is seriously injured by it. What! shall there be one part of the population to whom shall be reserved all the resources of the art of healing, and another part abandoned, *à priori*, to the errors, the faults, the ignorance of a class of inferior practitioners? Such a distinction is not admissible in France,—it would be odious—it is absurd. In place of seeking to diminish intelligence by imposing on it an inferior level, we must try to elevate it more and more; the science must be accessible to all, but all must be obliged to cultivate equally the science. Our faculties, with the conditions they require from their pupils, with their immense means of instruction, with their numerous examinations, can scarcely ever arrive at producing medical men, not inferior to their mission. How could it be wished to entrust the health of citizens to *officiers de santé*, deprived at once of the preliminary knowledge indispensable to medicine, and of the means of study; and to hasten to receive them without giving them the time to study. If in all arts half knowledge is injurious, *à fortiori* in medicine, in which the least errors may become irreparable and endanger the life of citizens.

To create superiority by an article of law is absurd, and repugnant to the nature of things. The defenders of the institution of the *officiers de santé* say, that there is no need of such high medical qualifications for the country; let them rest assured mediocrity will never be wanting. It is a law of humanity which the legislator cannot remedy; but it is his duty to stipulate for society all the guarantees that are at once possible and necessary. All these guarantees are contained in the diploma of doctor, which doubtless cannot give to all an equal capacity, but which gives to all the same legal value; as the stamp to gold, as the effigy of the prince to the coin of the kingdom. (*Rumours and murmurs. The orator is interrupted during some minutes.*) Such are, (resumed the orator,) the reasons in favour of the suppression of the *officiers de*

santé. But objections against this measure have not been wanting; we must now appreciate their value. First, they say to us, if you exact for a diploma of a medical man expenses so considerable, both of time and money, it will happen that many strong profound intellects will be forced from this career. Thence a double disadvantage, on the one hand, for individuals whose prospects will be lost; on the other, for the science, on which talents you reject might have impressed an increasing and glorious progress.

Further, these expenses, to which you will subject small fortunes, will necessarily induce the very natural desire of a proportionate remuneration; and as great towns only have the privilege of offering a brilliant prospect of ambition, this mass of doctors you are about to create, will crowd into the great towns, and leave the country places abandoned to quacks, who have not even intentions to allege in their favour, or else to sisters of charity, of whom the very praiseworthy zeal cannot disguise their ignorance and incapacity.

The objection reduces itself to this, that the too elevated prize of the doctorship will repel many men who might have been the glory of the science, and abandon country places to quacks.

The answer is easily given. And first, to arrive at a profession, promising at once ease, glory, and as much independence as is desirable from any other, without running risk to property or honour, assuring to all its members a good position in society, and, finally, an existence at least tolerable, is there really too great a sacrifice in four or five years of study and eleven hundred francs of expense? At a period when a numerous youth encumbers every career, when fortunes, rendered equal by the division of lands, by giving to all fathers of families the power of making economies, have inspired the taste, are we justified in fearing that medicine will want aspirants, and that the so moderate exigencies of the law obstruct too closely its entrance? Where is the profession placed as high in the social scale, which has need of fewer aspirants? We find every where the time of probation, under different names, the supernumerary period, the clerkship, &c. Let us take, for example, that celebrated school, by having been a pupil of which one deems oneself honoured, the *Ecole Polytechnique*, and compare it with medicine, under the double aspect of sacrifices and advantages. After the preliminary studies common to all liberal professions, the aspirant to the *Ecole Polytechnique* is obliged to dedicate two or three years to special studies, in order to prepare himself for the *concours*. The *concours* arrived, scarcely do they reckon upon one in five candidates being admitted as a pupil; such is the terrific chance, which may in a moment ruin the hopes of the other four. The pupil enters to the school, and is obliged to pass two years there. Now, who does not know what efforts

he will have to make during these two years solely to maintain himself in the ranks? Finally, the two years expired, he must now pass into the special schools, schools of engineering, of artillery, of naval instruction, and after these six or seven years of special studies, they are finally named to a place of lieutenant of the engineers, with salaries of fifteen hundred to three thousand francs, and with the prospect of an advancement always very remote and uncertain.

We impose too great expenses! In truth this is laughable. But in the other professions, the outlays, the caution money, the purchases of practices of lawyers, and of merchandise, are there not advances far otherwise considerable? And then, moreover, it is easy still to reduce these expenses; multiply the places of instruction; let the young people find nearer their families the instruction they are obliged to seek at such great distances.

For our part, what we alone wish, what is important to us, are guarantees; and on that account we call for more rigorous and more difficult examinations than at present exist, and do not fear, in proportion as the trials shall be more severe, that the candidates will be disgusted, and their number diminish; the rigour of the examinations of the Polytechnic school, by augmenting the consideration, reflected upon the candidates admitted, has only increased the emulation and the number of aspirants.

But, further, to remove such an objection, are our Faculties more deserted? Never was the influx so considerable. Will a complaint perchance be made of a want of medical men? With more justice is their too great number complained of. It is moreover said, that the rural parishes (*communes*) possess, generally, too little wealth, and instruction, and even distinction, to satisfy the intelligence and emulation of a doctor of medicine. What then! will it be said that the *officiers de santé* are less sensible than the doctors to all these advantages? The proof of the contrary is every day before our eyes; *officiers de santé* have quitted country places for towns; they practise in them on an equality with the doctors; they take great care to have themselves equally remunerated.

One of the wants of medicine in the present day is, beyond contradiction, a more equal distribution of medical men relative to the population, and, at the same time, with a more equal distribution of instruction among the profession. Medicine is not only an art, it is also an occupation, that should yield for each service rendered have its reward. Doubtless it would be desirable to arrive at this end, to enrich the poor, and people the desert parts of the country; but if these ameliorations can only be effected after a long lapse of time, there are yet certain prudent measures which may, to a certain extent, supply their place. Thus the number of doctors will be on the increase in country places when they shall no longer fear being confounded with the *officiers*

de santé; when each of them, penetrated with the dignity of his profession, shall no longer see arising near him an ignoble rivalry, and the science offered at a lower price. It must be confessed, indeed, that the greater part of the *officiers de santé* not having for their guide the recollection of a good education, do not always follow, in their private conduct, the most honourable course; and as to their science, far from augmenting the little knowledge they may have acquired, the isolation in which they live makes them frequently forget it too speedily. Hence a justly founded repugnance on the part of the doctors to mingle with such men. Put an end to this cause of their absence, and be sure that the country places will not remain long without medical men.

Another motive contributes to call them back to it. In an age in which the whole social problem resolves itself into the main thing necessary — medicine, which procures health, is one of the primary wants. The inhabitants of the country places do not seem to have as yet well comprehended this truth; and it may be truly said, that if any of them remain deprived of the aid of art, it is because they will not pay for it; and on this point, between doctors and *officiers de santé*, they make no difference. When instruction shall be more spread, the people will arrive at a better knowledge of the value of time, and consequently of the price of health; and the inconvenience we point out will much diminish, although never, perhaps, can we hope to see it entirely disappear.

Finally; it is said that the law has furnished a remedy for the presumed ignorance of the *officiers de santé*, by determining the cases in which they should be obliged to call in a doctor. But this problem of limits, which has been incapable of being resolved, even in theory, is far more difficult to resolve in practice, particularly for the serious cases, which the law has not been able to indicate. Thus, sometimes it is the *officier de santé* who will not call for a doctor, and sometimes it is the family, who fear having to pay two medical men; and thus, in the most threatening diseases, the *officier de santé* alone decides upon life or death. This is a fact renewed every day, the seriousness of which cannot be dissimulated. It is remarkable, that almost all the speakers who discussed, in the legislative body, the law of the organisation of medicine, were struck with the fear of this institution of *officiers de santé* spreading throughout France a mass of ignorant practitioners, which fears are but too much realised.

What must, however, be done to assure to the country places the requisite number of medical men?

Before the revolution, eighteen faculties had the right of admitting doctors in medicine; it is true that one blushed to belong to the half of them. At a later period, when there was a question of reorganising instruction, Condorcet

proposed the creation of nine colleges, to each of which should be attached a faculty. In the present day, we count no more than three faculties in France; but by erecting three others, as was proposed in the Chamber of Peers in 1826, namely, one at Lyons, one at Rennes or at Nantes, the third at Toulouse or at Bourdeaux, there would be a total of six faculties, which would supply every want. A complete system of education would be found in every point of the kingdom; the pupils, less removed from their families, will lose less the memory of their native place; the congregation of pupils, without being too numerous, would be sufficiently so to keep up emulation; we should have every advantage desirable.

But to draw from these establishments all the advantage we have a right to hope, the first thing to be done would be to assure to the professors a complete independence; their number, fixed by an article of law, must not be liable to change but by another law. The doctors admitted in the districts would soon naturally distribute themselves through them; moreover, advantages might be attached to certain admissions, by imposing upon the candidates the condition of establishing themselves in a rural commune (*parish*). Finally, the fee for practising in the country places should be much inferior to that required for populous towns.

Finally, as the most efficacious new measure for spreading upright and enlightened medical men in the country, we have to recommend the creation of cantonal medical men (*parish surgeons*).

Three great social interests demand the solicitude of the government; religious interests, moral and intellectual wants, material interests. It has long since provided for the first by the creation of curates (*curés*) in each village; a recent law, by multiplying the number of schoolmasters (*instituteurs*), has satisfied the second; the last still call for attention, and are not less worthy of being listened to.

To alleviate before hand the principal objections, let us hasten to say that the creation of these cantonal medical men will not be a measure of absolute necessity, or applicable to the whole of France. Numerous departments, more favoured than others by the richness of the soil and the beauty of the climate, attract a sufficient number of medical men for the wants of the population; those may already be excepted. Even in the poorest, it will not still be necessary to appoint them in all the cantons. We will say more, the want will only be felt in the smallest number. Take, for instance, L'Arriège, one of the departments to which this measure would be the most profitable; of twenty cantons, six at most will require cantonal medical men. In the *Haut Rhin*, where for ten years back this institution exists, and demonstrates its salutary influence, of twenty-one cantons, ten only have their special medical men. In the *Bas Rhin* the

same measure has produced equally happy results.

This may serve already to refute the objection which will be founded upon an enormous increase of expense. Follow now the project in its details. These cantonnal medical men could only be named by the municipal councils, approved by the council of the arrondissements. The communes, the canton, the department, would contribute each its part to the salaries of these medical men, which would reduce the expense, by distributing it; and already it would be partly met by the funds destined for vaccination, with which the cantonnal medical men would naturally be charged.

Add to this, that in proportion as the wealth of the country might increase, the number of cantonnal medical men may be diminished, and the salaries be lower. Moreover, in the crowd of industrious establishments, arising upon all points of France, many employ a sufficient number of workmen to have need of having a medical man attached to the establishment. Wherever another medical man exists, a cantonnal medical man becomes a superfluity. Finally, we may be permitted to look forward to a period, in which the recognised utility of this institution, will supersede the utility of hospitals in slightly populous towns. When this sentiment shall be fully entertained, will not the legacies, the donations, which in the present day are made to those hospitals, be naturally directed to the institution of the medical men of the canton, which will diminish by so much the expenses of the departments and of the communes?

Hitherto we have confined ourselves to reasoning and to general facts to prove the inconveniences of an inferior class of medical men and the possibility of satisfying all the wants of the public health by the doctors in medicine. Some statistical data will complete this demonstration.

In its memoir presented to the constituent assembly, the Royal Society of Medicine demanded, to ensure protection of the public health in France, a medical man for every four square leagues. In 1826, the commission, charged with making a report upon this subject to the Chamber of Peers, proposed to have a medical man for every square league;—this was falling into the opposite excess. We think that the real wants are largely satisfied when each circumference of two square leagues possesses its medical man; this is also the result given by the statistic of the departments in which the medical service is best supplied. From these calculations, France containing 30,000 square leagues, 15,000 medical men will be needed—(interruption). We would have wished to compute the number of patients to deduce thence the number of medical men necessary; but too much uncertainty is attached to the bases of such a calculation to lead us to dwell upon it. Indeed, certain populations are more frequently ill than others, where the mortality is not proportionably

greater; this is particularly observable in establishments of work gilders, painters, persons who work in lead, &c. The frequency of the diseases attacking them is such, that a society of mutual aid, established among workmen in London, failed solely from having received among its members, some individuals belonging to one or other of these trades. We shall content ourselves then with the number above-mentioned, 15,000 medical men; and by adding another thousand for the medical men who, given up to labours of the closet, are lost to practice, we shall arrive at a total number of 16,000 medical men. Can we then hope to have and to maintain complete this number of 16,000 doctors of medicine?

In 16,000 medical men, supposing them to commence practice at 24 years of age, death will carry off 362 in a year, according to the tables of mortality of the *Annuaire des Longitudes*. Now for several years back, the mean number of doctors of medicine admitted in the three faculties of France is 390. Thus the actual number of the admissions for the doctorship will already furnish enough, and more than enough for all the wants of the service; and further, it is demonstrated that the number of these admissions is continually on the increase from year to year. Add to this that many officers de santé, and of sons of officers de santé intend to become doctors, while the sons of doctors never content themselves with the title of officier de santé.

If, however, the necessity of destroying the institution of officiers de santé should appear to some minds less evident than to us, yet at least there must be a change of this title of officier de santé, which trails after a want of consideration too justly merited. We do not mean by this to make allusion to the officiers de santé of the present day; but the manner in which were received into this body all sorts of individuals after the disturbances of the revolution, and the disorders that have thence followed, have not conciliated the public either in favour of their delicacy, or in regard to their knowledge.

Still the commission persists in thinking that the institution in itself would not thence have fewer inconveniences. Let the medical juries be suppressed, it is said; we would have more severe examinations; but then why make them an inferior class, and why, while requiring from them the same instruction, give them any other title than doctors?

Whether they be named, however, officiers de santé or licentiates, the dangers remain the same. It will always be recognised as a principle to limit their right of practice, to interdict them in the treatment of the most severe diseases, and the practice of certain operations, to limit them to a portion of the soil beyond which their diploma will be without value. But who does not know that this limitation as to diseases is altogether impossible in practice? And as to the demarcation of the territory, can we conceive the absurd results it would bring

about, if it were maintained in its rigour? Must a family, by changing its commune upon the confines of two departments, be obliged to renounce its medical attendant, whatever confidence in other respects they may have in his intelligence? This class of medical men would then in some measure be reduced to the condition of Helots, and attached to the soil as formerly a serf to the farm he cultivated. Each step made in this path brings before us new obstacles.

Consequently, and particularly because this institution is injurious to the interests of society and of humanity, the commission, with an unanimous assent, concludes for the suppression of the *officiers de santé*.

As to the medical juries, the reprobation they have aroused is unanimous. It is known how they were instituted originally, to regularise, by means of a phantom of an examination, the right of practice, accorded, without right or reason, to a crowd of ignorant men and quacks. At least they confined themselves to conferring the diploma on medical men already practising; but, since that time, the law of Ventosean II. has invested them with the exorbitant right of receiving officers de santé, who present not even the proofs of studies in the schools, at the same time that their interests and their duty are put in collision by making the examiners be paid by those they examine.

Their abrogation ought to be immediate; and this necessity generally admitted is a new objection against the institution of the officers de santé.

Before arriving at this severe judgment, the commission has long meditated this question, has examined it under all its aspects, and collected all the reasons for and against, and it repeats that the abolition of the officers de santé is the expression of its unanimous and irrevocable determination.

(To be continued.)

French Medicine.

Of the Frequency of the Pulse in Insane Persons, considered in respect to seasons, atmospheric temperature, changes of the moon, age, &c., with a refutation of the received opinion concerning the decrease of the frequency of Pulse in old men.

TRANSLATED FROM THE FRENCH OF MM. LEURET AND METIVIER.

SECTION II.

The frequency of the pulse is not always in accordance with the atmospheric heat. Has the moon any influence over this frequency?

WHAT could have caused so marked a decrease in the frequency of the pulse? On the 6th,

towards eight o'clock in the morning, there was a new moon. Had this any decided influence over insane persons? Is the popular belief, which gives so great an influence to this planet over the human body, a truth?

Many philosophers of antiquity thought that matter, and by matter they mean a terrestrial substance, when abandoned to itself, was only disorder and confusion; that it was necessary in order that it should present regular phenomena, that it should receive its principle and direction from the influence of celestial bodies. Galen explains this theory, which he considers incontestible, in his work entitled, *A Treatise on the Decretory Days*. The moon, according to this author, has a very powerful action on the commencement, the continuation, and the crisis of diseases; her light, when exposed to it for a long time, occasions paleness and headach.

Many centuries after Galen, the belief of the action of the stars began to be weakened; it was confined to a small number of diseases, to those which were least known, the nervous diseases, and among these last insanity, being that which offered the most vagueness and incertitude, it was continued to be attributed to the moon. Persons afflicted with this disease were called lunatics; the words lunacy and insanity have become synonymous.

It has been reasoned, *à priori* on, this matter which belongs exclusively to experience, consequently nothing certain has been established. There have certainly been instances found in favour of this opinion, and which appear to prove its justness; but have there not likewise been met with facts contrary to this opinion, and of which account has not been taken?

It is necessary to come as low as 1792 to find an author who has examined with attention whether the moon has any influence over insane persons.

"For four years," says Daquin, "that I have been physician to the hospital of insane persons (at Chambéry), curious to discover whether they were subject to the power of the moon, I profited by all the resources which an assemblage of these unfortunate beings in a similar place offered. I kept a journal of ten insane persons only, whom I saw and visited assiduously without any interruption, each new moon, each first quarter, each full moon, and each last quarter; I only paid atten-

tion to these four principal points. From the observations recorded in my journal, it is very certain and well proved that insanity is a disease over which the moon exercises a constant and real influence. The new moon and the last quarter are the periods which have the most powerful influence. The first quarter and the full moon exercise the least influence over the access of insanity, and I feel convinced that frequently, if I may be allowed to express myself so, it was only a negative influence, that is to say that the insane at this period were more calm and tranquil.

"The whole of my observations relative to the influence of the moon on insanity, were always made on the precise day of each lunar change; this exactitude enabled me to perceive that there was constantly a greater influence on these days than the intermediate ones; this influence was even perceptible the evening before the day on which the lunar change took place, and was even strongly marked the day after the change."

We therefore perceive that, according to Daquin, insane persons have an increase of agitation during the new moon, and likewise during the last quarter: they have a calm during the first quarter and the full moon.

This proposition, founded upon an observation of four years, and to all appearance so well proved, is nevertheless inexact, and Daquin himself refutes it in the second edition of his work. The full moon is no longer a negative point, it has become an affirmative one, it agitates the insane. There remains no doubt of this on the mind of the author, who adds, as a last proof, "I this day, 20 germinal an xii, made a general visit of all the insane of the hospital, and I perceived that something exerted a great influence over their minds; the moon was this day new, as likewise in peregrée; but I never saw, since the time I have studied them, a degree of exaltation so fully pronounced as at this time, without one exception, whatever might be the kind of alienation with which the patients were afflicted. A similar fact, continues the author, has been the effect of all the observations I have hitherto made; it is an incontestable fact, appears decisive, and of great weight."

Our numbers have been of great use to us in appreciating the value of the opinion of Daquin. In an agitated insane person the pulse acquires frequency; this cannot be

doubted, and our daily observations have proved it. A person whose pulse was 144 in a minute in an agitated state, was not more than 58 when it came to its calm condition. If a powerful and general cause exerted its influence over our patients, if this cause had arrived at the point named, it would not undoubtedly have escaped our observation, for it would have necessarily accelerated the pulse, and we counted each pulsation.

Instead of an augmentation, we had, on the contrary, a considerable diminution on the days of a new moon, and this notwithstanding an elevation of temperature; for the full moon we had a decrease of temperature corresponding with a diminution in the number of individuals whose pulse was frequent.

Daquin must therefore be mistaken. We can only attribute his error to his having made his observations on ten persons only; to his not having employed any proper method by which he might be able to note with precision the degree of agitation of his patients; to his not having made his visits daily; and, in fine, to his not having taken into account the state of the temperature. This observation, made on the 20 *germinal*, and which appears to him so decisive, proves absolutely nothing, as this day corresponds to the 9th of April, the heat of spring being sufficiently high, especially at Turin, to agitate insane persons.

M. Esquirol, who has examined with the greatest attention how far the moon exercises an influence over lunatics, declares that such an influence, as stated by Daquin, is altogether false; he (Esquirol) does not acknowledge any other influence than the light of this planet, which, by exciting these persons, keeps them awake and causes illusions of their senses.

The following is a report with regard to the changes of the moon, with the number of pulsations, and the number of individuals whose pulse were more frequent on these days.

Changes of the moon.

Frequency of the pulse.

Last quarter	New moon	First quarter	Full moon
85-67	81-62	80-55	79-80

Individuals having their pulse more frequent (calculated upon 100).

57-12	34-72	34-72	23-52
-------	-------	-------	-------

If our observations had stopped at these

Y Y

four lunar points, we might be induced to conclude that the last quarter of the moon agitated lunatics; the new moon agitated them, but in a less degree; in fine, that the first quarter and the full moon occasioned a calm: this conclusion would be erroneous, for this would be attributing to the moon what appertains to the temperature.

Does not this explain the decrease in the frequency of the pulse which Daquin found took place on the eve of a new moon and on the day itself?

OXFORD MEDICAL DEGREES.

We condense the substance of a code of regulations relating to degrees in medicine, just issued by the University of Oxford, by which our readers will perceive, that the spirit of intolerance is as violent as ever, and the whole regulations are eminently calculated to diminish the number of graduates, to drive the great majority of Englishmen to the Scottish Universities, and to prevent dissenters, and all who refuse, on conscientious grounds, to take the oath of supremacy, from acquiring the degrees of Bachelor or Doctor in Medicine. It has long been a standing maxim with the Universities, to keep medicine as an heir-loom in families of the aristocracy, a piece of wisdom as strenuously and as absurdly maintained by the London College of Physicians. These bodies cannot change with the times, but stand still, while all the rest of the scientific world is in rapid motion. We feel convinced, however, that the time is at hand, when Parliament, and not the Government, will open the eyes, not only of the College of Physicians, but also of the Universities. Now for our condensation of the regulations.

The heads of the University admit the exercises for degrees in medicine are not suited to the times, and therefore they abrogate them, and decree that

I. Candidates for the degree of Bachelor in Medicine shall submit to the public examination required for a degree in Arts and in Civil Law, and after this examination, spend three whole years in the study of medicine.

Masters of Arts and Bachelors of Civil Law, provided they submit to the examination hereafter mentioned, and have passed twenty-eight terms from the time of matriculation, may take the degree of Bachelor in Medicine.

II. That the Examiners for Bachelor in Medicine be the Regius Professor of Medicine and two other doctors of the University, to be named by the Vice Chancellor, and approved of by the House of Convocation.

That in the absence of the Regius Professor a substitute be appointed by the Vice Chancellor.

That the Faculty of Examiners, before the examination, be sworn to act impartially.

III. That the examination take place the second week in Trinity Term, at a place to be appointed by the Vice Chancellor.

That the examination comprise Theory and Practice of Medicine, Anatomy, Physiology, Pathology, Materia Medica, Chemistry, and Botany; and that the candidates be examined in the works of Hippocrates, Aretæus, Galen, or Celsus.

The whole examination is to be made on one day, and may be in Latin or English.

The Examiners to give a testimonial.

Masters and Bachelors of Arts, &c., may be present.

The candidate shall place in the hands of the Regius Professor, fourteen days before the day of examination, certificates on the above subjects, and for hospital attendance, which must be approved by a majority of the Examiners.

IV. Fees to Examiners.—The candidate to deposit six pounds for the two Doctors: the Professor to be remunerated as formerly.

V. That candidates for the degree of doctor shall be bachelors, and have studied three years more.

VI. That candidates shall write and read a thesis before the Faculty or Examiners.

VII. That Doctors, &c. of other universities, desiring to be incorporated, must have answered for the degree of Bachelor of Arts in their respective academies, and then undergo the examinations, &c. required by this statute.

VIII. That doctors may practise every branch of medicine within the precincts of the University; no other person, unless authorised by the Vice-Chancellor. That surgeons be authorised by the same.

That doctors, after having taken the oath of supremacy, receive a licence to practise in all parts of England.

That these regulations commence before Trinity Term, 1834.

These, like the regulations, of all our medical incorporations, are selfish and obscure. It is not clearly stated whether a candidate for the degree of M. B. is to be a graduate in arts, or whether he must have matriculated at the university. Neither is it clear what lecturers are recognised, nor is it evident whether the lectures delivered in the metropolitan or provincial schools are sufficient. Previous to these regulations, the lectures delivered at Cambridge and at Trinity College, Dublin only, were received.

Upon the whole, these regulations exclude nine-tenths of medical students, and compel them to resort to other universities for advantages that ought to be afforded them in their own. The idea of granting a doctor's degree on the presentation of a thesis, is preposterous, as every one knows that such an essay may be composed by any individual for the candidate. There is no examination for the degree; and a Fellow of the College of Physicians, on presenting himself a few years since for that testimonial, was left to read a novel, while the examiner was occupied in filling up his degree. Nevertheless, such men as these are placed over the graduates of all other universities in the world, and it is considered ultra-radical for the great body of physicians in London and elsewhere to denounce such a system.

UNIVERSITY OF ST. ANDREW'S.

Regulations for granting Medical Degrees by the Senatus Academicus of the University of St. Andrew's.

UPON a motion, made at a previous meeting, the Senatus Academicus took a-new under their serious consideration, the mode of conferring Degrees in Medicine and Surgery; and, with the view of requiring from candidates for that honourable distinction, a course of study calculated to prepare for the full and enlightened discharge of their professional duties, and of affording to the public the most ample security that no degree will be conferred until it has been ascertained, by a minute and scrupulous examination, conducted by the Professor of Medicine, in conjunction with other distinguished members of the medical profession, being resident Fellows of the Royal Colleges of Physicians or Surgeons in

London, Edinburgh, Glasgow, Aberdeen, or Dublin, that the candidates have suitably profited by attending the prescribed classes and hospitals, and are in every respect qualified to practise with advantage to the community, adopted the following regulations, which they agreed to publish in all the Medical Journals of Great Britain, and to communicate to the highest medical authorities:—

I. No candidate shall be admitted to examination till he has subscribed a declaration that he is twenty-one years of age, and has produced satisfactory evidence that he is of unexceptionable moral character.

II. The candidate, if he be not in possession of the degree of A.M., must produce certificates of his having had a liberal and classical education, and be ready to undergo an examination as to his proficiency in the Latin language.

III. The candidate must produce certificates that he has regularly attended lectures, delivered by Professors in some University, or by resident Fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, Glasgow, Aberdeen, or Dublin, for, at least *four complete sessions, during four years, on the following branches:—*

1. Anatomy.
2. Practical Anatomy.
3. Chemistry.
4. Theory of Physic, or Physiology.
5. Materia Medica and Pharmacy.
6. Principles of Pathology and Practice of Physic.
7. Surgery.—(*Each of the above courses to be of six months' duration.*)
8. Practical Chemistry.
9. Midwifery and Diseases of Women and Children.—(*Each to be of three months' duration.*)
10. An apprenticeship, or six months' attendance in the shop of an apothecary, or in the laboratory of a public hospital or dispensary.
11. Attendance at a public hospital, containing not less than eighty beds, for, at least, twelve months.

For degrees in medicine—clinical medicine.
For degrees in surgery—clinical surgery.

Two three months' courses of either to be considered equivalent to one six months' course.

These regulations will be invariably ob-
y y 2

served, except when the candidates are possessed of a surgeon's diploma from London, Edinburgh, Glasgow, Aberdeen, or Dublin; have been in regular practice previous to the year 1830, or have served as medical officers in his Majesty's Army, Navy, or East India Company's Service, in which cases three years' attendance on the above courses will be sustained.

The *Senatus Academicus* have, in the meantime, appointed as conjunct Examinators with the Professor of Medicine:—

Robert Liston, Esq., Fellow of the Royal College of Surgeons, Edinburgh, Surgeon to the Royal Infirmary, and Lecturer on Surgery.

J. A. Robertson, M.D., Fellow of the Royal College of Surgeons, Edinburgh, and Lecturer on Surgery and Materia Medica.

J. Mackintosh, M.D., Fellow of the Royal College of Surgeons, Edinburgh, and Lecturer on Midwifery and Practice of Medicine.

Alexander Lizars, Esq., Fellow of the Royal College of Surgeons, Edinburgh, and Lecturer on Anatomy.

William Gregory, M.D., Fellow of the Royal College of Physicians, Edinburgh, and Lecturer on Chemistry.

Any three of whom, along the Professor of Medicine in this University, to be a quorum.

It is resolved, that there shall be three periods during the year for graduation, viz. the last Tuesday in April, the first Tuesday in August, and the last Tuesday in December.

Every candidate for these degrees must communicate with the Professor of Medicine, personally, or by letter, and furnish him with a list of the Certificates he intends to produce, fourteen days before the stated period of examination, to prevent disappointment, delay, and expense. Each candidate, after he shall have afforded sufficient evidence to the University, as to his course of study, and paid the fee of graduation, will be informed of the time and place of his examination, which must be conducted before the *Senatus Academicus*, or a Committee of that body.

The whole proceedings shall be submitted to the consideration of the *Senatus Academicus* by the examiners. Should the University be satisfied, the degree will be conferred on the candidate by the rector in the hall of the public library of the University, and the diploma will be signed by the members of the University and the examiners. Should any

candidate be found unqualified, he will be re-mitted to his studies till the next period for conferring degrees; and when he again presents himself, he will be required to produce satisfactory evidence that he has been diligently engaged, during the interval, in improving himself, and, if possible, attending additional lectures. In the event of being re-mitted to his studies, he shall forfeit one-third of the deposit money, which, however will be accounted for to him, when he passes his examinations successfully at a subsequent trial.

St. Andrew's, Dec. 9th, 1833.

Comments on the above.

The degree of M.D. has always been looked upon as the highest honour in medicine, and to obtain it hitherto, it was necessary that the student should present certificates of attendance upon the lectures of professors in universities. No other qualification was admitted. The operation of this law has in many respects tended to the disadvantage of medical science, and to the public injury, Can any one for a moment suppose that the lectures delivered by Sir A. Cooper or Mr. Abernethy, were not as likely to benefit the student, to make him fit to practise his profession, as those delivered by any professor whatever, and yet attendance upon the lectures of these gentlemen formed no qualification for receiving the highest medical honours.

Again, the patrons of universities have not always been the best judges of the requisites to make a professor. Hence, they have sometimes appointed to chairs men perhaps of high talent and celebrity, but who proved incompetent teachers; and thus the best interests of science, universities, and of the public, have been unintentionally sacrificed.

Again, the appointments of professors are for life. Age will creep on, and with it our faculties and powers will fail; but although a professor may become incompetent, still his class must be attended, and thus the cause of science and the public good must suffer.

Now, the professors, if good teachers, will, from the honourable situation they hold—from the other advantages connected with their office, command a large class, even if the field of competition were open, although with inferior or incompetent teachers the case might be otherwise.

The University of St. Andrew's has, with great judgment and propriety, admitted, as qualification for degrees, the attendance upon those classes which are admitted by the Colleges of Surgeons of London, Glasgow, Dublin, &c.; and these are placed upon the same footing as the lectures within the walls of universities. This is a great boon to students, to the public, and to the cause of medical science. Its operation will not rest here, it must extend to the other universities. In self defence they must make their regulations more liberal than they are at present. That the degree will be valued, the presence of the Senatus of St. Andrew's at the examination of the candidate, and the high character of the examiners they have appointed, will be a sufficient guarantee. These gentlemen must be responsible to the public for the strictness of the examination which the candidate must undergo.

X.

THE APOTHECARIES' ACT.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—As the period is now fast approaching at which Parliament will assemble, and as it is allowed by most practitioners, that inquiry ought to be made into the existing state of the profession in all its branches, I am desirous, through the medium of your respectable Journal, of calling the attention of my professional brethren to the 3rd Clause of the Apothecaries' Act, by which the Master and Wardens, for the time being, or their Assistants, are authorised to do and perform very disagreeable duties * * * *

Now, whatever necessity might have existed, from the enactment of this clause, in the reign of King James the First, when grocers were allowed to sell drugs, it appears clear to me, and I think must be allowed to be so by every unbiassed mind, that Parliament did not consider such necessity to exist in the year 1815, for, towards the conclusion of the act, (see clause xxviii.) we find that druggists are excepted, a fact so strong and conclusive, that it is wonderful the Company should not have abandoned the right as regards the private practitioner; but let us inquire into the intention of the act itself, and a question will naturally present itself; for whose benefit did the legislature confer this power on the said society? for the benefit of the public certainly,

and not the society. When bad or improper drugs are sold, or when drugs are improperly administered, who are the suffering parties? the public; then this power was intended as a protection to the public. I think, therefore, it must appear evident to every candid and reasoning mind, that this inquisitorial power (whether rightly placed I shall not stop to inquire) has been grossly misdirected; the inquiry ought merely to be made of the retail dealer in drugs, not the legally qualified practitioner of medicine, who, for the most part, neither retails drugs nor dispenses any prescription, except when he is in attendance to watch its operation, and however strongly the Master and Wardens may express their desire to exalt the character of the profession, I submit that this mode of proceeding appears not well calculated to attain that object; it is at variance with the principles of sound morality, and hangs by the profession as a brand and a stigma; to honest men it is unnecessary, to honourable men it is a dishonour and a degradation; moreover, be it remembered that the persons who execute this odious right, are men whom you cross in your daily practice, and without directing my observations to any one personally, I may be allowed to observe that it affords an envious man an opportunity of gratifying private pique, by making frivolous objections against his neighbour's establishment. But this is not all, the master, wardens, and assistants, it must be borne in mind are members of a trading company whose interest it is to extend the sale of drugs. By asking to be shown a variety of preparations, they can cause the private practitioner to keep a much larger stock than his practice requires, and it is evidently their interest to find fault with drugs supplied by any establishment save their own; if this surveillance is to be continued, surely it would be but fair to place it in the hands of those who are in no way connected with pharmacy. This language may by some be considered too strong, and therefore I again disclaim anything approaching to personality, but when we see the retail druggist, an uneducated man, in every street in the metropolis, not only selling drugs and dispensing prescriptions without controul, but also prescribing in all cases, as well medical as surgical, frequently practising midwifery, not to mention the minor operations of bleeding, cupping, and so on, I think a little allowance ought to be made for one who feels that

he is visited for the sins of others. It really appears singular that the eyes of legislators should not yet have been opened as to the glaring defects of this extraordinary act on the one hand, and its unnecessary and unconstitutional severity on the other. These evils ought to be remedied, and I hope the great body of general practitioners will shortly enter into some means of making their voice heard in parliament on the above subjects, as also all others connected with the welfare of the profession.

I am, Gentlemen,
Your obedient servant,
MEDICINÆ EXERCITATOR.

Nov. 29th, 1833.

OBSERVATIONS ON PERICARDITIS.

BY A STETHOSCOPIST.

I LATELY read, in your publication, an account of two cases of pericarditis that had occurred in the Middlesex Hospital. The writer has also prefaced these valuable pathological facts with some remarks on the physical as well as stethoscopic indications of the above disease. My object in addressing you is chiefly to put your correspondent in possession of a few additional facts, recently observed in the progress of this insidious and fatal malady; and if, in return the writer can afford an explanation of the morbid sound of the heart on the principles of attrition, which he seems disposed to credit, I shall be thankful to receive them.

A patient was admitted on the 5th of Nov. into the Middlesex Hospital with acute rheumatism of the fibrous form; no morbid action was detected in the heart. On the 12th, she was observed to be somewhat haggard in countenance, though complaining now of slight pain only in the wrists, and none in the chest. On listening to the heart, a distinct "bellows sound" was heard to attend its systole; she was immediately put under a strict course of mercury, and lost blood by cupping to the chest. On the 22nd, the pulse was intermittent, the morbid sound still heard; but, added to this, there was noticed the following singular change. The patient being on her back, and the stethoscope being placed over a spot corresponding to the junction of the third and fourth rib with the sternum, a duplex sound was distinctly heard, consisting of the above-mentioned "puff," and a rough grating

sound, similar to a carpenter's plane: the latter could only be heard in the above spot, whilst the bellows sound was evident in every part of the præcordial region. The stethoscope was kept over the sternum, and the patient made to lie on her right side, then on her left, and lastly the trunk was placed upright; in neither of these postures was the rough sound heard, but only the other; it was also heard over the first dorsal vertebra of the spine.

I must here remark, that during the whole progress of this attack of the pericardium she has never, to this day, once complained of pain, nor has she allowed that any was caused by pressure in the præcordial region or epigastrium. Her rest has never been disturbed; her posture is indifferent; and the usual symptoms of pain from the shoulder to the elbow is absent. She is now (Nov. 30th) walking about the ward in good health, as she expresses it; the two sounds are quite as distinct as when they were first noticed; the heart is still intermittent; her features are sharp and haggard. Though this patient may be apparently cured to an inexperienced stethoscopist, we cannot be morally certain in this, or any other case of pericarditis, that the cure is complete until the patient is capable of resuming the usual avocations of health without distress to her chest.

Before proceeding to comment on the above facts, I beg to state that this patient, and the man alluded to by your correspondent, are not the only two cases of this disease in which I have been unable to trace the slightest general signs of pericarditis. Rheumatism has been greatly prevalent during the last six weeks, and so indeed has metastasis to the heart; but so far from the usual symptoms of pericarditis having been well developed, there has been with few exceptions scarcely a case in which those signs noted by authors as common to the disease have presented themselves.

It is on the stethoscope that we must principally rely for information in this obscure disease; and every experienced practitioner will allow that this morbid sound is never absent in acute pericarditis.

On the first occurrence of the "bruit de soufflet," in the above-mentioned case, the pericardium was undoubtedly inflamed; the remedies employed controlled this inflammation, and on the 22nd day we could speak pretty accurately as to the condition of the

membrane, viz.—that it was partially adherent; being so, it would not suffer that friction of the opposite surfaces which must, according to the writer's views, have caused the fresh sound now heard; had it done so, surely one of the postures in which she was placed must have aided the friction, and therefore have increased the grating noise; but no,—it removes it altogether.

It is an invariable law operating in the progress of inflammation and its results, that where lymph is effused for the purpose of adhesion, a mechanical obstacle exists to prevent such a desirable end taking place, there being a simultaneous effusion of serum, which tends to keep the opposite surfaces apart, and render that very occurrence which your correspondent is disposed to view as productive of the morbid sound almost impossible; for I would ask him, how is it to be explained in the case of Scott? The bag of the pericardium was distended with citrine-coloured serum,—could any attrition there take place? In the second case the sound never left the heart after its first establishment, and never altered in character to her death, and here the pericardium was universally and firmly adherent;—how was motion over the heart's surface to take place here?

Had the writer been desirous of explaining the cause of this valuable diagnostic sign on the principle of attrition, he could not have selected two cases more illustrative of the futility of his argument than the above. Why they are ill chosen, I will leave your readers to decide. Concerning the case treated successfully by Dr. Watson, the writer adds the following interesting fact:—"that there were three feeble contractions with a loud grating sound, followed by three others, stronger in impulse, and devoid of morbid sound;" for an explanation of which phenomenon, he adduces the following,—“that as the heart struck feebly against the chest, the opposite surfaces were better able to come into such contact, that a mere rubbing together could ensue; whilst, when the impulse was strong, it so displaced the lymph, that attrition could not result.” Now, I first ask him,—Why did the excitement of the patient remove the “bruit” so instantaneously? 2ndly, Did the heart simultaneously with the disappearance of the sound become accelerated?—The latter question I can safely answer in the negative, though your correspondent has failed to notice the circum-

stance at all, if he recollects this fact, which I am sure he must if he listened attentively to its action, how can he explain the first point upon the principle of attrition, seeing no sensible alteration was caused in the systole of the ventricle? The point of the præcordial region, at which the greatest impulse is given, corresponds to a spot from three-quarters of an inch to one inch below the mamma; the above sound was heard midway between the sternum and nipple, somewhere near the base of the organ;—let me ask then, how the impulse of the heart at the fifth rib could possibly influence a sound produced at the base of the organ. Again, presuming the lymph was sufficiently firm in texture to cause this rasping by its attrition, can we readily assent to the idea of instantaneous displacement of such lymph, which must necessarily be endowed with the properties of firmness and adhesiveness, without involving ourselves in a most abstruse mode of reasoning, the absurdity of which will be apparent to every one who reflects calmly on such an explanation.

It is too true that lymph may be spread over the whole pericardium, and be mammillated in structure; it may exist in greater quantity over that spot where the morbid is heard; but at the same time it must be shown that the lymph is not separated from the two surfaces by serum, and is also so immoveably adherent, that a rough sound could be produced by its friction; for if it were so, that most essential process which nature sets about establishing as her first step towards tentative reparation would be annihilated. If there exists lymph on the pericardium, and neither adhesion or complete absorption of such rapidly ensues, the surface of the membrane becomes endowed with the property of secretion; this fluid, according to Dr. Latham, may be thin and scanty, and of the palest yellow colour, by degrees becoming more consistent and copious; whilst this process is going on around a vital organ, reparation by adhesion cannot possibly ensue, more and more accumulates, the heart becomes troubled in its action, the disturbance to the vascular system is too great to be long endured, nature's processes are perplexed and overthrown, and before one set of vessels can remove the serum and another set organise the lymph, the heart's action is suddenly arrested, and death instantaneously ensues.

If nature is enabled to effect adhesion between the opposite surfaces, it rarely happens that firm and general adhesion is the result; on the contrary, long slender bands of lymph are thrown out from one surface to the other, or the layers may be a mere, reticulated membrane, as thin as a cobweb, such, indeed, that it would never convey the notion of its being the cause of the harsh grating sound noticed by your correspondent.

I had an opportunity of examining the heart of a young man who died from recent pericarditis a few days ago. The medical gentleman who attended him is a practical stethoscopist; and he informs us that so late as in June last, there was a harsh grating sound attending the systole of the ventricle, and a bellows murmur besides; and that there were other evidences of hypertrophy of the organ. The patient was constantly livid in countenance, and greatly distressed in his breathing: he died anasarcous. The whole pericardium was adhering feebly to the heart by a series of firm bands of lymph; in some parts the membrane was of a deep scarlet colour, and over the right auricle the shreds of vermilion-coloured lymph gave the appearance of loose tapestry; but the most important point remains to be described,—the valves of the pulmonary artery had become firmly adherent, so as to form one thick membrane, with a central opening capable of admitting a small pea; the foramen ovale was also patulous, and the aorta remarkably small in calibre. In this instance, then, the harsh sound noticed in June last must have been caused by the peculiar condition of the sigmoid valves.

What then is the immediate cause of these preternatural sounds, and the mechanism by which they are produced? I conceive the explanation must be afforded by morbid processes going on within the heart. There does appear to be in all cases of pericarditis a co-existing inflammation of the internal lining of the organ; and the pathology of acute and chronic diseases of the pericarditis shows this fact.

An individual is attacked with inflammation of the serous covering of the heart, he is actively treated, and the disease is arrested in time to allow nature to remove all those productions of inflammation; he is apparently cured; but let him return to the habits and exertions of health, and a recurrence of his

palpitation and dyspnoea will bespeak the certainty of disease still within the heart.

Inflammation of the internal lining is usually limited to those portions which are reflected upon themselves, and constitute the valves, whilst the membrane covering the fleshy walls becomes involved in the disease only as a consequence of the other. We may readily conceive that these membranes will become stiff, lose their elastic character, and intumescence ensue, which will give rise to constriction of the valvular apparatus on every attack of inflammation.

Now this inelastic and puckered state of the valves or internal lining of the heart does most assuredly produce a rough grating sound, even though all the cavities bear a due proportion to one another.

Some time since a patient in the Middlesex Hospital, under Dr. Watson, was afflicted with paralysis of the portio dura, and subsequently died of apoplexy: in his case the systole of the heart was attended with a sound analogous to the rubbing of two pieces of silk together, nothing could be harsher than the noise: it was found to have been produced by a thickened state of the membrane of the left ventricle, just as it is reflected off the muscular wall to form the semilunar valves; so that when the ventricle was closed, a distinct sharp ridge could be felt around the mouth of the aorta; every other part of the organ was perfectly healthy.

From these facts then do I argue that there is caused by pericarditis an alteration in the capacities of the orifices of the heart, the circumference of the opening will be more or less circumscribed, and the correspondence between the cavity of the ventricle and its mouth being changed by such inflammation, the blood in its flow onward passes, by the increased impulse of the ventricle, through a narrower opening, thus causing a sound modified in degree and intensity by the previous healthy or thickened condition of the valvular apparatus.

I have now to apologise for having trespassed on your pages; but I have done so more from a desire to elicit any further remarks from your readers on this interesting point, than with a view of laying any novel theory before them, which might only tend to perplex instead of unravelling the intricate chain of symptoms attending this serious, and too often fatal, disease.

MEDICAL REFORM. — DR. JOHNSON
AND THE EDITOR OF THE MEDICAL
GAZETTE.

WE have uniformly advocated the necessity of waiting for the result of a Parliamentary inquiry into the condition of medical education and practice, before the profession, or any influential portion of it, should be called upon to propound a scheme of Medical Reform. Under the apprehension of that inevitable scrutiny, the whole body corporate of medicine is at present in a state of fever; and local inflammations, which are rapidly disorganising the ancient tissue, are in active operation on the surface, and in the centre,—at St. Andrew's and at Oxford.

What may, then, be the actual state of the profession a month hence, at least in its future prospects, it is very hazardous to pronounce. Much of the present evil is, we fear, beyond the reach of instant reformation; and where rights of practice have been already conceded to an education, now, on all hands, confessed to be inadequate, we must wait for a generation to pass away, before the evil can be totally extinguished, and console ourselves, meantime, with studying the bills of mortality: still, with regard to the future, the medical corporations have it in their undoubted power, even without the interference of Parliament, to innovate an improved curriculum of education. But waving the despotic constitution of those governing bodies, and those evils, which are far beyond the reach of their mending hand, the evils arising from the conflicting legal rights and dis-

abilities of the several classes of practitioners, willing as we are to applaud good intentions however tardy, we cannot regard such changes as have been lately made and are likely to be imitated, as any satisfaction of the general demand for a uniform systematic course of education throughout the United Kingdom, with an abolition of all rivalry but that of accomplished professors. If we may be allowed the metaphor, the tattered garb of patches, with which the profession is now clad, "in variety of wretchedness," may be exchanged for a coat of many colours, but still the simple and just taste of the age will object that there is "nothing of a piece about it*."

To return to the discussion of the Westminster Medical Society, we must observe, that the ruse of that able tactician, Dr. Gregory, signally failed: every independent member of the profession, whether at the first full meeting, when his proposition was advanced and scouted, or at the second when it was lost by a ballot, (presuming the proceeding legal,) discountenanced his scheme as utterly intolerable. On this point there was, there could be, no difference of opinion. Dr. Somerville's scheme was considered by many eminent members of the Society, not sufficiently developed to warrant its adoption even by those who favoured the principle; whilst others looked upon the proposal of any specific measure, in addition to a prayer of general inquiry, as premature, if not inconsistent. Our quarry is too high to allow us to stoop upon the vulgar cabal, which is alleged to have interfered with and stifled the deliberate opinion of the Society: there certainly was much noise and intemperance in the decision of the affair; but we cannot, in conscience, impugn that de-

* Otway's Orphan.

cision. A petition to parliament, detailing the grievances of the profession in precise and strong but temperate language, and praying an inquiry into their causes, and redress of this national evil, from the grand inquest of the nation, is *datum* sufficient for the solution of the problem : grant but inquiry, and the good cause is secure.

This proposition of a single Faculty for the whole kingdom, has led to a reckless imputation upon the consistency of a most honourable member of the profession, which calls for a word or two. Dr. Johnson, who proposed the resolution, although he deprecated the notion of dictating to parliament what course it should pursue prior to any inquiry, exposed with a happy combination of humour and reasoning, the absurdities of the ordinary distinction in the education of physicians and surgeons ; and, as a necessary consequence, of any classification between them, other than what the tastes or habits of individual practitioners, in a large and condensed society, will necessarily lead to. If upon so plain a position any still entertain a doubt, we refer them, with no ordinary satisfaction, to one of the most philosophical introductory lectures that was ever delivered upon the objects, history, and prospects of medicine, which enriches the pages of our last week's *Journal* (No. 99) ; and we hail the dawn of brighter days in that statement of Dr. Stokes, that every day is tending to produce a fusion of the profession, in the spirited institutions of the Sister Isle.

These opinions were not new to Dr. Johnson ; and in the 6th volume of the *Medico-Chirurgical Review*, he republished an admirable article, which he had written and published long before, for the purpose of comparing it with Mr. Lawrence's famous speech on the same subject. Dr. Johnson's published opinions,

then, must have been well known to the hackneyed Editor of the *Medical Gazette*. The very same volume of the *Doctors' journal*, contains that Editor's circular upon the Treasury Minute touching Hunter's Museum, from which, by the by, it appeared the Lords of the Treasury were not aware of the existence of such a degraded body as Licentiates of the College of Physicians. But it fortunately happened, for the purposes of malice, that the same volume contained an ultra-tory anonymous review of Mr. Lawrence's speech, which it suited the short-sighted policy of the Editor of our contemporary to attribute to Dr. Johnson, and, thus propped, to assail one of the most consistent and manly reformers in the profession, as a truckler and time-serving partisan ! It is well known that the review in question was the production of the late Dr. Dill, a gentleman of talent, whose abilities were unfortunately chequered with an inordinate zeal, which often led him to support party opinions, and express them with a warmth, which upon reflection he regretted :—who does not remember the alarming article upon Cholera in the *Quarterly Review* ? and yet this same writer, who did his worst to convulse the nation, ultimately joined the anti-contagionists. But it is unnecessary to expose, at greater length, the futility of these puny efforts at detraction.

LUNATIC ASYLUMS IN IRELAND.

OUR attention has been called to the management of the District Lunatic Asylums for Paupers, which have lately been established by Government in Ireland, by the perusal of a very sensible and well-timed pamphlet, from the pen of Dr. Jacob, of Maryborough, the physician appointed by Government to one of these establishments in his native

town *. - This gentleman has shown talents and industry, and seems to be actuated by a sense of duty to his afflicted patients and the cause of medical science, which prove him worthy to succeed to his father's more than provincial reputation as an able physician of the past age. We have read, with great interest, the result of his examination of different Lunatic Asylums, and highly approve of the regulations he proposes to adopt in that over which he has, or ought to have, control. There is no doubt, these establishments, under the care of intelligent physicians, will afford an opportunity of adding much to our information of the occult forms of insanity, an infliction to which the healing art has been but latterly deemed universally applicable. To medical readers it is unnecessary to insist, that derangement of the mental powers is, in general, a consequence of some lesion of the corporeal frame:—but, we fear, the public, and more especially the Irish gentry, who have considerable influence over these national institutions, are not fully aware of the fact. In the words of Dr. Uwins †, “Madhouses ought to be divested of their peculiar character; instead of ‘Mausolea of mind,’ they are merely receptacles for that kind of bodily sickness, which prevents the proper exercise of the mind.”

We collect from Dr. Jacob's pamphlet, that there is, in each of these institutions, an officer, called a *manager*, who, without any other education than a little familiarity with madness in the large establishment in Dublin, sets himself up as a *moral governor*, and, like the Irish Tutor, has,

each of them, *his system* for treating insanity; and considers the physician as an almost useless appendage, to be consulted as occasionally as in a parish workhouse. These things must not be: higher interests than the respectability of the profession are at stake; and if the Irish gentry are not enlightened enough to know that it is the peculiar province of the physician to prescribe the treatment, moral or physical, of mental diseases,—we think a memorial to the Government would set the matter right.

ST. GEORGE'S HOSPITAL REPORTS.

WE regret that our friend at St. George's was led into error in stating, that the former medical attendant had most shamefully mismanaged the case of sloughing of the penis. We have heard the particulars of the treatment, and nothing could have been better. No member of the profession could have treated the case more judiciously. A physician and surgeon had attended, and advised the man, who had no relatives, to go to the hospital.

WOUNDS IN THE TRACHEA.—PHYSIOLOGY OF DEGLUTITION.

BY W. DU HEAUME, ESQ.

FROM experiments it appears to me, that an important circumstance has been omitted in the physiological account of deglutition. My limited reading may, however, have readily led me into error. During swallowing an expiration is made, and the air escaping through the rima glottides at the time the substance passes over it, is, instantly after the substance has passed, made sensible at the opening of the nares. This, I conceive, is one use among several others of the large quantity of air left in the lungs, after an ordinary expiration, so much of which can be expelled by a voluntary effort. If this be correct, it will explain why substances, taken into the mouth, pass out of a wound in the trachea, situated below the rima; and I do not know how this can be satisfactorily explained otherwise. How often this occurs is well known. Dr. Colles, of Dublin, in his lectures last winter, related the

* Observations and Suggestions on the Management of Maryborough District Lunatic Asylum, submitted to the Consideration of the Governors. By John Jacob, M.D., Physician to the Institution, &c. Dublin, 1833.

† On Medical Disorders. London, 1833.

case of a man, who had a small wound of the anterior thyro-hyoid ligament, through which the fluids, taken into the mouth, escaped. The man died in eight months. The treatment this view of the subject would suggest, is the total prevention, if possible, of the escape of air through the wound, during the taking of food or drink.

Glasgow, 14th December, 1833.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, December 21, 1833.

MR. PETTIGREW in the Chair.

The Medical Gazette, its misrepresentation—Dysphagia—Dr. Gregory's Ballot.

THE minutes of the last meeting having been read and confirmed,

Dr. James Johnson rose, and said, "as it is usual in the House of Lords and Commons to take notice of the reports of speeches, I trust that this Society will allow a zealous but humble member, the privilege of commenting on strictures passed upon his speech at a late meeting. A medical Journalist in his publication of this day, (he alluded to the Editor of the Medical Gazette) has accused me of tergiversation, and of having contradicted myself, in declaring opinions on medical reform, which were contradicted in the Medico-Chirurgical Review, of which I am the Editor. Though my accuser is well aware of the fact, that, in that work, there are articles furnished by different individuals, he most erroneously considers that I am the author of every thing that appears. There is nothing more common than difference of opinion entertained by different writers on the same subject; more especially on such a question as the difficult one of medical reform. Illustrations of this fact are constantly afforded in our ablest political reviews,—as the Quarterly and Edinburgh. The article attributed to me was not written by me, but by the late Dr. Dill, of the Fever Hospital; and in the same volume is one by myself, infinitely more radical than any thing I have stated in this Society (*hear, hear*), and diametrically opposed to that referred to (*hear, hear*). The Editor did not choose to notice this, as it did not suit his purpose; but I shall republish it within a week, and leave the profession to judge of my con-

sistency as a medical reformer (*hear, hear*). In fact, it appeared in 1817, was republished in 1827, and shall re-appear in a few days, and behold the proof of my inconsistency! Some years since there was a great hostility between the Lancet and the Medico-Chirurgical Review, which I deeply regretted, as injurious to the fame of the profession. I discontinued it, and from that moment I have been assailed by the Medical Gazette, though I am utterly unconscious of ever having given the editor the slightest cause of offence. Even on a late occasion, he solicited my vote as candidate for the office of Physician to St. George's Hospital: I gave it him cheerfully, and his strictures of this day show his gratitude.

The Chairman observed that he felt sure the society entertained the highest respect for the opinions of Dr. Johnson on every occasion, and the manner in which he had acquitted himself at the last meeting elicited well merited applause from the numerous meeting—(*hear, hear and applause*). He regretted the absence of the Secretary, for were he present, he (Mr. P.) would complain of the short notes of the proceedings of the last meeting, because some interesting facts were mentioned, well worthy of a place in the society's records. He alluded to the change of the hair after the small-pox.

Dr. Gregory said that Dr. Copland and himself had seen the case related by the Chairman and bore his testimony to its accuracy.

Dr. Johnson then called the attention of the society to three cases of dysphagia, in two of which the patients complained of pain at the cardiac orifice of the stomach, though the stricture was high up in the œsophagus. One eminent surgeon was afraid to pass a bougie, and the other did so, and greatly relieved the sufferer.

Mr. Dermott explained the cause of the pain at the cardiac orifice by reminding the meeting of the muscularity of the œsophagus at that part, and of the strong sympathy between all parts of that tube.

Mr. Hunt thought it of primary importance to keep the state of the constitution in view before passing the instrument, as he had known cases in which death followed in the course of two or three weeks afterwards. He wished to ask Dr. Johnson whether he did not consider that spasmodic dysphagia was of more frequent

occurrence than that caused by change of structure.

Dr. Johnson replied in the affirmative, and added that hysterical and dyspeptic women were very subject to it. One of the diagnostics of permanent stricture was a copious discharge of ropy mucus.

Mr. King was of opinion, that the introduction of a bougie was not so dangerous, as had been imagined. He had repeatedly employed the instrument without any bad result.

Mr. Bevor related a case in which a bougie was sometimes passed to the cardiac orifice, but never into the stomach; and at other times it could not be introduced. The patient died, and on examination a large ulceration was discovered.

Mr. Pettigrew stated that he had seen a preparation, brought from the country by Mr. Langstaff, in which the stricture was at the edge of the epiglottis, and nearly closed the œsophagus. It had fallen to his lot to have seen several cases in which strong coffee was swallowed with more ease than any thing else.

Mr. Quain detailed a singular case of a gentleman, who had constantly witnessed the sufferings of a friend afflicted with stricture. So great was the impression on his mind, that after some time he experienced great difficulty of deglutition, and died of spasmodic dysphagia.

Mr. Dermott referred to the anatomy and physiology of the œsophagus, and explained the nervous sensibility of this part. He was inclined to believe, that permanent stricture was more likely to take place at the narrowest part of the canal, namely, its commencement.

Dr. Johnson agreed with the last speaker, and said that he had no doubt but one of the cases he related arose from spasm only.

A gentleman mentioned a case of an intemperate man, in which inflammation of the mucous lining of the canal was the cause of death.

Several other cases were described, in which the patients experienced great difficulty, in swallowing certain kinds of food.

Dr. Epps then proposed the following resolution, which was seconded by Dr. Johnson, and after some opposition from Dr. Gregory, was carried.

“That the sense of the Society be taken upon the question, whether it be con-

sistent with the regulations of this Society, that a ballot be taken upon a resolution upon an evening succeeding to the declared passing of the said resolution, more particularly as another resolution was discussed and passed on the same evening after the resolution referred to was declared passed by the Chairman.”

MEDICAL SOCIETY OF LONDON.

Monday, December 23, 1833.

MR. KINGDON in the Chair.

The Egg-cup case—Pathology of Typhus.

THE whole evening was occupied in traversing the same ground as at the last meeting, with the exception of a few remarks on the pathology and proximate cause of typhus. The Society then adjourned until Jan. 13th, and the President gave notice that he should summon a meeting to be held on Tuesday the 7th of January, to receive and discuss the petition for medical reform.

Portuguese Hospital Reports.

(Continued from page 669.)

Gun-shot wound of the Chest—Ball lodged.

R. J., a young and healthy private soldier in the service of the Queen of Portugal, was wounded in the back, Nov. 17th. The ball (musket) entered through the middle of the left scapula and penetrated his chest, fracturing one of the ribs. The first few days the symptoms were those of high inflammation of the chest, great pain, cough, and fever, which symptoms were allayed considerably by large bleedings, the establishment of suppuration, &c. The discharge of matter from the wound became very abundant and continued so. Irritative fever came on, and in nine weeks he died.

I was not able to examine this patient with the stethoscope, from much the same circumstances as prevented my doing so in the last case.

Autopsy ten hours after death.—The cavity of the chest was quite full of purulent matter, and the lung collapsed to the size of one's fist. The lung did not appear to have been injured by any pieces of bone or the ball. The ball

was found within the chest, in some degree imbedded in an intercostal space, about two inches below where it had entered.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Concussion of the Brain—Fracture of the Cranium—Death.

THOMAS CALLOW, a carpenter, was brought to the hospital, Dec. 12th, at 11 o'clock, A.M., having been struck a quarter of an hour previously on the vertex, by a heavy parapet stone. He fell from a height of five or six feet, and grazed the skin over the left temporal region by falling on another stone. He was taken into the accident ward (Oxford) and on examination by the house-surgeon, he presented the following series of symptoms. The pupils of both eyes were contracted; the breathing slightly stertorous, and there was general violent convulsive action of the muscles of the body, requiring several assistants to hold him. The head was found to be of a remarkable shape (which we understood to be natural), the frontal eminences and the convexities of the temporal bones protruding greatly, and giving a very unusual appearance to it, to those who remarked it for the first time. There was a slight graze over the left eye, and over the squamous portion of the left temporal bone; a puffy swelling could be felt beneath the cranial integuments, evidently resulting from effused blood, but no fracture or depression of bone could be detected either on that side or the opposite one corresponding to it, where the swelling beneath the integuments was less. A gentleman who was present believed that he could feel the ridge of a fracture or depression, but on this point we could not satisfy ourselves.

He was immediately bled from both arms, and ℥xiv . of blood were abstracted, the blood presenting no remarkable appearance. Shortly after his admission the pupils of the eyes became widely dilated, the breathing very irregular, laboured, and stertorous, with general loss of muscular power, more particularly of the muscles of the left side of the body, the intercostal muscles of the right and left sides acting freely in respiration. Mr. Hawkins (whose accident week it was), was immediately sent for, and on his arrival found all the above symptoms manifestly increasing, the pupils becoming more widely dilated; the breathing more laboured and stertorous, and the paralysis of the upper and lower extremities increasing. He examined the patient's head very carefully, but could not detect any fracture or depression through the cranial integuments. Mr. Brodie and Mr. Babington being in the Hospital at the time, Mr. Hawkins requested their opinion on the case. On reviewing the symptoms, Mr. Brodie advised that an incision should be made down to the

bone, and the trephine applied to the *right* side of the head (the paralysis and loss of power being more evident on the *left* side of the body), which if it did not relieve the symptoms could not increase them. An incision was accordingly made over the posterior and superior edge of the squamous portion of the temporal bone when a fracture of the bone was discovered running downwards from the vertex, the trephine was applied, and on a portion of the bone being elevated, there was found a coagulum of blood lying between its inferior surface and the superior surface of the dura mater, and from the cerebral membrane being puffed up and giving no signs of pulsation, it was conjectured that some internal vessel of the brain was ruptured, and was constantly pouring out its blood upon it; a further portion of bone (near the anterior inferior angle of the right parietal), in the direction of the fracture, was removed with Hey's saw, and the same appearances as above stated presented themselves. The temporal artery, and a branch of arteria meningea media were divided and allowed to bleed for a short time before they were secured by a ligature. No relief whatever to the symptoms resulted from these operations, the patient, indeed, appeared evidently worse, and Mr. Hawkins was on the point of trephining the bone on the opposite side, when the attention of every one was drawn to the apparently dying state of the man, and Mr. Brodie and Mr. Babington gave it as their opinion that no possible good could result from it, and Mr. Hawkins therefore desisted from the further performance of an operation which every one foresaw would be of no service or utility whatever.

Mr. Hawkins remarked that it was very probable the fracture extended through the base of the skull, across the sella tunica of the sphenoid bone, and that the parietal bones were driven in and forced out the temporal ones. With respect to the application of the trephine over the course of the meningeal artery, many surgeons (Mr. Liston, Mr. Lawrence, and others) he knew were averse to it; there were others, however, who held an opposite opinion, and, for his own part, he thought it was an operation which might always be performed without incurring any risk or danger. The patient, when he did die, would die of suffocation, from the nerves of respiration ceasing to perform their functions. We saw the man again at 3 P.M., the respiration was slow, laboured, and stertorous, accompanied with a short catch, somewhat resembling hiccough. The muscles of the larynx acted with violent spasmodic action at each effort of inspiration, and the intercostal muscles had a tremulous convulsive action given to them. The impulse of the heart gave a thrilling sensation to the hand over the whole auricular region; the action of the ventricles was sharp, and the apex, especially, could be felt distinctly striking against the parietes of the chest; the pulse was thrilling.

He died at 5 p.m. About an hour before his death he brought up some blood and mucus from the throat.

Autopsy twenty-one hours after death.—On removing the cranial integuments the edges of the coronal suture were found separated to the extent of half an inch, and at the part where the blow was received, which was a little to the right of the median line of the cranium, and over the coronal suture, a depression was seen, and a fracture extending directly backwards from the suture into the right parietal bone, of from two inches and a half to three inches in length, was noticed. The squamous sutures of the temporal bones were somewhat separated by the blow, and causing a fracture which extended downwards on each side into the basis cranii, and met in an even line in the sella turcica of the sphenoid bone, thus entirely dividing the anterior from the posterior portion of the skull all round, the fissure of the fracture was about half an inch wide. There was a considerable effusion of coagulated blood between the external integuments and the cranium, more particularly on the left side. The membranes of the brain were not torn, but there were large masses of coagulated blood over the lateral surface of each hemisphere (more particularly the left), between it and the dura mater, and at these parts the external convolutions of the cerebrum were more or less blackened and broken down. The lateral ventricles contained each a small portion of serum. The exterior and inferior surface of the cerebellum was broken down and engorged by the violence of the *contrecoup*, and the arbor vitæ was pale in appearance, and flabby in consistence. A large portion of coagulum was found in the occipital basis of the cranium. The commencement of the spinal marrow, pons varolii, pons olivæ, &c. did not present any particular abnormal appearances.

WESTMINSTER HOSPITAL.

Cancer of the Breast.—Amputation by Mr. Lynn.—Cure.

MARIA MEEK, æt. 50, of robust habit and dark complexion, applied to Mr. Lynn for advice about the commencement of last September, under the following circumstances. She has been married about twenty years, but has had no children. About twenty months previous to her application, she received a very violent blow from a door, which was suddenly driven open, and the key of which came in violent contact with her right breast. Some time after, her attention was arrested by a slight swelling in the situation where she had received the injury; but the swelling progressed very slowly until about eight or nine weeks ago, when it increased alarmingly in dimensions, and by the advice of her friends she applied to Mr. Lynn for his opinion as to the means most likely to afford her relief.

Mr. Lynn, after a careful examination of the diseased breast, pronounced amputation as the sole chance of relief. Sir Anthony Carlisle completely disapproved of such a measure, and mentioned the case of a woman who had cancer of the breast, and lived upwards of thirty years after the cancer had first set in, ultimately dying, not of the disease, but of old age.

Mr. White, on seeing the case, gave his opinion decidedly in favour of the operation. He stated his reasons for such an opinion to be, the quickness of its growth, and, secondly, the fact of the surrounding parts being free from disease. These he considered as circumstances which perfectly warranted an operation. Accordingly, on the 14th of September Mr. Lynn proceeded to perform the operation of removing the diseased breast. On examining the breast a short time previous to the operation, we found a tumour about the size of a melon; it was exceedingly hard, and entirely free from connexion with the surrounding parts. It was exquisitely sensitive, and appeared to be in a state of ulceration. There was some enlargement of the veins; she complained of darting pains.

Mr. Lynn having made two semicircular incisions, detached the cancerous breast in a very few minutes. Three or four arteries were taken up, and the edges of the wound approximated by means of long slips of adhesive plaster, which were brought round the neck.

It was generally understood that the present was the last operation which Mr. Lynn intended ever to perform in public, and as such excited some interest. The steady, intrepid, and rapid manner of operation which Mr. Lynn (who is very closely bordering on ninety years of age) exhibited, was not a little astonishing to the persons present.

On the night of the operation, the patient was tolerably easy, but she complained of the bandages being rather tight. Her bowels were costive, and she was ordered some saline aperient medicine.

September 18th. Bowels regular; pulse scarcely perceptible. Wound dressed yesterday; adhesions commencing. Some cordial medicines were administered by the house-surgeon, and with good effect. Mr. Lynn, however, entirely disapproves of the exhibition of stimulants soon after an operation. He also took occasion to warn the pupils against giving patients animal food after operations; he had frequently seen the very worst consequences ensue on such injudicious treatment.

The patient now rapidly recovered her strength, and at her own wish left the hospital on the 25th of September in a very favourable condition.

On the 23rd November, she came to the hospital to show herself, and by her own statement was in perfect health. As might be expected, she was somewhat in a weak state,

but in every other particular she was completely at ease. Her countenance was cheerful, and she seemed deeply grateful for the cure which had been performed on her.

ST. BARTHOLOMEW'S HOSPITAL.

Porrijo Lupinosa.

A YOUNG lad, about fifteen years of age, was admitted under Mr. Lawrence with an extensive scabby eruption on the head. These scabs were of a circular form, and of a slightly yellowish colour; their edges somewhat elevated, and they bore a strong resemblance to the seeds of lupines, from whence they derive their name. The size of each did not exceed that of a shilling.

The treatment consisted in shaving the head and in constantly washing the scabs with soap and water. The eruption has been touched with the *argentum nitratum*, and purgatives administered. Under this treatment the patient is now convalescent.

NUMBER OF STUDENTS AT THE LONDON UNIVERSITY AND KING'S COLLEGE.

	University.	K. College.
Anatomy	224	132
Demonstrations	213	130
Chemistry	171	140
Midwifery	49	98
Medical Jurisprudence	45	63

The numbers attending Practice of Medicine, Materia Medica, and Botany, are not given, but we believe the classes at the University are much more numerous.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, December 19th.

Thomas Abraham	Grundisburgh.
Henry Clapton Barnard	Hereford.
William Henry Bellot	Stockport.
Thomas Ebbage	Bungay.
Cornelius Garman	London.
Edgar Henry Longstaff	Lincoln.
John Lindley	Derby.
Jas. Morrell Coventry Primus	Powys.
John William Potter	Ongar, Essex.
Charles Jacob Hare Ray	Woburn Place.

LITERARY INTELLIGENCE.

DR. EPPS has in the press a Case of Epilepsy of twenty years' standing cured, with the Treatment and Remarks thereon.

Preparing for publication, the Study of Osteology, or History of the Bones of the Human

Body. Illustrated by Five Imperial Folio Plates, from Albinus and Cheselden. By J. CASTLE, F.D.S., Trin. Coll. Camb., &c.

BOOKS.

CASES Illustrative of and Confirming the Remedial Power of the Inhalation of Iodine and Conium in Phthisis and various disordered states of the Lungs and Air-passages. By SIR CHARLES SCUDAMORE, M.D.; F.R.S., Honorary Doctor of Medicine of the University of Dublin, &c. &c. 2nd edit. 8vo. pp. 227. Longman and Co., London. 1834.

An Essay on the Physiology of the Iris, with a different view of its Relations and Sympathies from the one usually received; and an attempt to establish a New Theory of the Action of Light upon the Eye. (Read before the Literary and Philosophical Society of Manchester, November, 1833.) By JOHN WALKER, Assistant to the Manchester Eye Institution, &c. 8vo. pp. 16. Webb and Sims, Manchester; Wrightson and Webb, Birmingham; Simpkin and Marshall, Renshaw and Rush, and John Churchill, London. 1833.

Anatomical Plates, by GEORGE DARBY DERMOTT, Esq., Lecturer on Anatomy and Surgery. *Reference to the Dissection of the Front of the Thigh*, Plates 1, 2, 3.

These Plates have a large sale, and well deserve it.

Illustrations of all the most celebrated Medical and Surgical Works, comprising a complete System of Morbid and Descriptive Anatomy, with separate title pages. Six Plates. Weekly. Dulau and Co.

The cheapest, and as accurate plates, as any ever offered to the medical profession.

CORRESPONDENTS.

Dr. Stokes's Lectures.—We shall commence the year with the truly scientific and practical lectures of Dr. Stokes, and insert one every week until the course is completed.

Mr. Holmes's case next week.

Dr. Thomson's paper on the Apothecaries of Great Britain has been received.

Mr. Swift.—Dr. —'s lectures have not reached us as yet, Dec. 26th, though delivered some weeks since.

The Surgeon-General's fourth and fifth lectures have been received.

Mr. Dermott's communication is under consideration.

A Member of the Westminster Medical Society.—The comment is too caustic,—it is more potent than St. John Long's lotion.

Mr. Pickford's communication is received. Dr. Ryan has removed his residence to No. 4, Great Queen-street, St. James's Park, Westminster.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

VOL. IV.

LECTURES ON THE PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

Delivered at the University of London,

Session 1832—1833.

LECTURE I.XX., DELIVERED MARCH 18, 1833.

GENTLEMEN,—Although mercury may not be absolutely essential to the cure of the venereal disease, yet as long as it shall continue to be a remedy of greater power for the prevention of secondary symptoms than any other known medicine, its reputation, as a means of curing this disorder, will always stand high. Mercury is used either *topically*, that is, as a direct application to sores, nodes, and other local affections, or *constitutionally*, being introduced into the system either through the medium of the stomach or the skin.

Amongst *topical* mercurial preparations, the *black wash* is in very common use for venereal sores, both primary and secondary. It should vary in strength according to circumstances; when I was a student the proportion of the ingredients was a drachm of calomel to a pint of lime water; but now it is frequently made stronger, and sometimes as much as ten or fifteen grains of calomel are put into each ounce of lime water. With regard to the manner of using it:—if the sore, or sores, are on the outside of the prepuce, a piece of lint is dipped in the lotion and applied to them, but if the sores are under the prepuce, the introduction of lint into that situation would create too much irritation, and the lotion may therefore be occasionally injected under the prepuce with a small syringe. The *yellow wash*, used in the same manner, contains two grains of the oxymuriate of mercury in each ounce of lime water.

Mercurial ointments are not in general very good applications for venereal sores of any description; certainly they are not equal, in point of efficacy, to many other applications. Sometimes, however, the *unguentum hydrag-*

gyri nitratis, blended with the unguentum cetaceum, or with zinc ointment, in various proportions, may be usefully employed.

Another manner of using mercury topically is that of *fumigation*. For this purpose, we employ an apparatus that is furnished with an iron heater, and a copper tube, by which the fumes can be conveniently directed to the part affected. And in order to be able to do this better, we have both a straight tube and a curved one, the latter being particularly convenient for ulcers in the throat. The mercurial fumigating preparation in general use is *cinnabar*, or the *red sulphuret of mercury*, from which when it is placed on the heater, a subtile grey powder is sublimed, which lodging on the sore, is found in many instances to produce a very beneficial effect upon it. I have seen sore-throats, chancres, and other ulcerations, which had resisted every plan that could be devised for weeks and months, assume a healthy appearance, and heal up rapidly, after fumigation had been tried a few times. To know this truth is important; much more so than to be able to say exactly how far the specific power of mercury is here concerned in the production of the good; certainly the fumigation of a sore of moderate size is not likely to have any effect on the constitution; I should suppose that the method cannot generally operate on this principle. Perhaps, with the exception of fumigation, I may say, as a general remark, that topical mercurial applications are not considered at all more useful than others which contain no mercury. The black, or calomel wash, is frequently made use of; but I do not know, that it possesses more efficacy than several other astringent lotions, which have not a particle of mercury in them.

With respect to the introduction of mercury into the system from the surface of the body; this can be accomplished either by rubbing mercurial ointment into the skin, or by mercurial fumigation of an extensive portion of the surface of the body. Friction with the ointment, the ordinary method, the most generally adopted as requiring no machine for the purpose, is practised by the patient himself, who rubs some part of his body, which is fre-

quently the inside of the thigh, for a quarter of an hour or twenty minutes before the fire, sometimes once a day and sometimes twice, with half a drachm or a drachm of the ointment. The quantity of ointment employed, however, varies in different cases, according to circumstances. Sometimes a scruple, sometimes half a drachm, and in other instances double this quantity, or even more, may be employed at a time. This is termed *rubbing in*, because a portion of the ointment seems as if it had been made to enter the pores of the skin by the friction, so as to be absorbed; but, except where the patient is very easily affected, what remains on the surface of the skin should not be wiped away, the patient putting on a pair of flannel, or other drawers over it. I ought to mention however, that sometimes friction and the rancidity of the ointment together (for you will seldom meet with mercurial ointment perfectly free from rancidity), will bring out numerous pimples, and even erysipelatous inflammation, and then he should be directed to repeat the friction on another part, and not to leave any of the ointment on the skin. Friction with mercurial ointment has commonly been preferred in this country to all other plans of treating the venereal disease; first, because it has been conceived to be the most efficient mode of treatment, and the mercury in the ointment being combined with a very small proportion of oxygen, has usually been given as one reason for the alleged fact; secondly, it causes less risk of disturbing the stomach and bowels than internal preparations; thirdly, it is frequently considered to be the only certain way of getting a sufficient quantity of mercury into the system; this is the common opinion. Preparations of mercury, given by the mouth, are apt to disorder the stomach, and bring on diarrhoea. I have long suspected that the latter was the principal cause that rendered mercurial friction so favourite a practice; for while the doctrine prevailed, that it was necessary for the cure of syphilis to fill the patient with mercury, to saturate him with it from head to foot, and to salivate him unmercifully, the stomach and bowels often revolted against the scheme, which absolutely could not be carried into execution in every instance, by preparations designed for internal administration. It was then chiefly by means of mercurial friction, that the old fiercely salivating practitioners could get into the system as much mercury as they wished, not that they did not also give internal preparations as far as they could. I believe that the doctrine of the superior efficacy of mercurial friction is founded on prejudice, and that, unless the stomach and bowels be disordered, and the constitution cannot be affected with moderate doses of the blue pill, it is seldom indispensably necessary to have recourse to this uncleanly practice. In certain cases, you are indeed obliged to direct mercurial frictions, as when the stomach and bowels will not bear even a

small quantity of mercury, which occasionally happens, or when it is necessary to resort to more plans than one, in order to bring the system under the influence of the mineral. Under these, and perhaps a few other circumstances, you may be called upon to prescribe frictions as well as internal preparations.

Fumigating the surface of the body is not at present deemed so necessary and eligible a method of putting a patient under the influence of mercury, as some of its admirers once endeavoured to instil into the minds of the profession. It is attended with considerable trouble and inconvenience; it requires a particular machine, somewhat resembling a sedan-chair, in which the patient sits with his head out of an opening at the top of it. At the bottom of the machine is an iron heater, on which a preparation of mercury is thrown, which is sublimed and covers all the surface of the patient's body; of course, he sits naked in the machine. The preparation of mercury, employed for this purpose is the grey-oxide. Another mercurial powder, that was recommended and used by Mr. Abernethy, was calomel that had been put into liquor ammoniac, and then dried. After having undergone the process, the patient puts on his shirt or flannel-waistcoat, and goes to bed. The reasons formerly urged in favour of the practice, are that it is less fatiguing to a debilitated person, than mercurial frictions, and that the system can be more quickly brought under the influence of mercury than by any other way whatsoever. This seems to have been Mr. Abernethy's opinion, who was once very zealous for fumigations; but afterwards relinquished them. With regard to the reasons given for the use of fumigations, that mercury may thus be employed, when the patient is in the weakest state, and that he may be mercurialised without the fatigue of friction, or the risk of disordering his stomach and bowels with internal preparations; the argument, though plausible, has not really much weight; because, when the health is seriously impaired, we are seldom justified in giving mercury at all; and at all events, it should then never be introduced so rapidly into the system. But, gentlemen, if you feel inclined to try that plan, it may be useful to know, that it is not necessary for the patient to go into the machine at all; he may turn his flannel waistcoat and drawers inside out, and put them into the machine to be fumigated. They will become covered with the fine powder sublimed from the heater, and, on being worn afterwards, will salivate the patient as well as if he had gone into the machine himself. This fact was ascertained, I believe, by the late Sir Charles Blicke of St. Bartholomew's Hospital.

Of the internal preparations, the *pilula hydrargyri*, or common blue pill, has the greatest reputation in this country; it is one of the mildest of all the internal preparations; you know that the common dose of it is five grains; but, frequently, you are called upon

to give a larger dose, and sometimes a smaller ; from three to ten grains may be stated to be the ordinary average quantity proper to be given in the twenty-four hours. You may join it with other medicines, according to circumstances, as with the sulphate of quinine, the extract of conium, and various other medicines, especially opium. We often combine the blue pill with a small quantity of opium, in order to lessen its tendency to affect the bowels.

The *hydrargyri submurias*, or *calomel*, is not very extensively employed in England for the cure of syphilitic complaints, though it is a favourite medicine for this purpose abroad, especially in Germany. Even in England, in one form of the venereal disease, calomel is usually preferred, viz. in syphilitic iritis. This preparation, like the blue pill, may be joined with other medicines, as with guaiacum and the sulphuret of antimony, which we find is the case in the *compound calomel pill*, which is not unfrequently prescribed in venereal affections, but especially in those which demand merely slight alterative treatment.

The *oxymuriate of mercury*, or *corrosive sublimate*, is a very powerful medicine as you well know, and, if it be incautiously given, it may readily poison the individual. The dose is small, the average quantity, usually given, is one-eighth of a grain, twice or thrice a day. When mixed with distilled water, it dissolves more readily if a small proportion of the muriate of ammonia be added. There are instances, in which from half a grain to three quarters of a grain may be prescribed in divided doses to be taken in a day. The *liquor hydrargyri oxymuriatis* of the London Pharmacopœia, contains the eighth of a grain of the oxymuriate in two drachms. When you wish to give it with bark, you may dissolve one grain of it in an ounce of the tinctura cinchonæ, of which a teaspoonful is the proper dose.

The *hydrargyrum cum cretâ* is the mildest preparation of mercury ever employed in this country, and, on this account, it is preferred in cases, where we wish to exert a very slight mercurial influence on the constitution. It is deemed the best preparation of mercury for infants who are born with syphilis about them ; examples in which it is found to prove equally safe and efficient.

One caution is necessary when you are giving patients mercury ; namely, you should watch its effects very attentively ; for it will act very differently on different individuals. Some will be violently salivated with a few grains of blue pill, as happened in a case which I am now attending ; the patient, to whom I am alluding, only took ten grains of blue pill in divided doses, yet she is most violently salivated, and her mouth severely, almost dangerously, ulcerated. Some will be violently salivated by a scruple of blue ointment ; while others will use from one to three drachms of it daily for months together, with no manifest effect on the function of the sali-

vary glands, bowels, or other organs. The doses of mercurial preparations must then be regulated by circumstances ; indeed it is wholly impossible to give any precise rules on this head, on account of the different effects of the mineral on different individuals. I may say, however, that the safest plan is always to begin with small quantities of mercury, watching the effects of the medicine, and being guided by them.

The action of mercury on the animal economy is very powerful ; the nervous, the absorbent, and the sanguiferous systems are all considerably affected by it ; an universal irritability is excited ; there is a quickness of the pulse, and a feverish state of the whole constitution brought on by it ; the secretions are all increased, especially those of the skin, kidneys, and salivary glands. *Salivation*, or an increased secretion of saliva, and a soreness and swelling of the gums and mouth, are the effects, which surgeons have long been accustomed to observe with attention ; for these are usually regarded as tests of the remedy having a sufficient influence on the system effectually to cure the complaint, for which it is given ; not merely to cure the *primary symptoms*, but give the patient the best possible chance of escaping the *secondary ones*. In fact, this is the main object of giving mercury ; we know that we can cure the primary symptoms without mercury ; and were these alone abstractedly considered, perhaps, we should never be justified in salivating the patient at all. But the great and solid argument for mercurialisation is, that, without it, the patients will be more likely to be attacked by secondary symptoms. Well, this affection of the gums and mouth, and this increased action of the salivary glands, are generally regarded as tests of the constitution being sufficiently influenced by the remedy for the attainment of the grand indication in view, namely, not merely that of removing the primary complaints, but the still more important one of preventing the occurrence of secondary symptoms.

The first change perceived is a copper taste in the mouth ; the breath acquires a peculiar fetid smell ; sometimes letting out a secret which the individual may not always wish to be known, namely, that he is under a mercurial course ; his watch and the money in his pocket will also, in consequence of the transpiration of the mercury from the surface of the body, become coated with mercury, so as to let out the same information to persons who are observant ; and you know, that in every family there is always a vigilant party on the look out for such things, especially the women (*a laugh*). When mercury is given in ordinary doses, a swelling and sponginess of the gums are generally brought on—an inflammation and tenderness of them ; an uneasiness, pain, and looseness of the teeth, and more or less inflammation of the mucous membrane of the mouth. When the constitution is remarkably susceptible of the action of

mercury, a very small quantity of it will sometimes throw the patient into a violent salivation, attended with ulceration and even sloughing of the parts in the mouth. The gums and mucous membrane of the mouth will ulcerate; the edges of the tongue will be in the same condition; and the tongue itself may swell to an enormous size, and be pressed against the teeth; in consequence of which deep ulcerated indentations will be formed in it; I have frequently seen the ulceration so severe as to extend through the cheek, and even produce extensive mortification of the parts, with necrosis of the jaw. It is this risk which should always induce you to begin with small doses of mercury, and to watch their effects. The quantity of saliva, discharged from a patient in a complete salivation, is sometimes very copious—from three to four pints may be poured out in the twenty-four hours. I never look upon a patient, in a state of violent salivation, without a feeling of disgust, for I know that it is a practice completely unnecessary—nay, it is highly prejudicial; and I should therefore say, it is a cruel mode of administering mercury, by no means justified by anything, which is made out respecting the true character of the venereal disease. I am happy to say, however, that such practice is not now common in London; but whoever had the opportunity of seeing the mercurial courses pursued in the foul wards of the London hospitals a few years ago, will never forget the horrid scenes there displayed. At that period an immense number of deaths were actually produced by the abuse of mercury. You must therefore, gentlemen, be cautious in your manner of giving this powerful mineral; for if it be introduced too quickly or copiously into the system, you will sometimes not be able to stop the salivation for a considerable time. Thus, the poor woman, whom I am now attending, was at first under a physician, who gave her ten grains of blue pill in divided doses: this quantity, as I have told you, produced a most violent salivation, with loss of all the teeth, and ulceration, and sloughing. Here no blame could attach to the practitioner; there must have been an idiosyncrasy concerned, or an extraordinary susceptibility of the action of mercury, such as could hardly have been contemplated. But, even in common constitutions, severe ulceration will sometimes come on before you are able to check the mercurial action; and, I may say, that we know of no means that will check a salivation so quickly as mercury will bring it on. The usual plans resorted to for this object are exposure to cold air, the exhibition of saline purgative medicines, and the use of gargles, especially those containing the chloride of soda. When there is ulceration, you may employ the same gargle, or one of muriatic acid.

There are, gentlemen, one or two interesting questions connected with this subject, namely, how far salivation is a right criterion of the influence of mercury on the constitution? and

how far it is a means of judging whether that influence is such as affords the patient the best chance of secondary symptoms being prevented, and the primary affection cured in the most expeditious and favourable manner? Perhaps I may say, as a general remark, that salivation is a good test for these purposes; but the remark is liable to exceptions; for some individuals cannot be salivated by any quantity of mercury, and yet their venereal complaints will get well with tolerable facility; while others may be salivated by a few grains of blue pill, and therefore long before any adequate mercurial impression can have been made on their disorder. But supposing salivation to be generally a good test of the proper influence of mercury on the system, then the question arises—to what degree are we to understand that salivation is to be carried? Certainly not so far as to bring on ulceration and sloughing of the mouth, or even to produce so profuse a discharge of saliva as to make it run out of the mouth in streams: this is not at all requisite as a test of the adequate influence of mercury. Neither, gentlemen, are you to imagine, that you are to give mercury in the same quantity during the whole time that the medicine may be proper: sometimes it may be necessary to suspend the use of the medicine in consequence of the gums getting too tender: and, under other circumstances, where the constitution is difficult to affect with mercury, you may be required to increase the quantity of it. Indeed, there is only one general rule which I can give you, and which was, I think, given by Mr. Hunter, namely, that you must be guided, in the administration of mercury, partly by its influence on the disease, and partly by its influence on the constitution;—you must watch its effects both on the disease and on the constitution.

Notwithstanding all the light that has been thrown on the venereal disease by the investigations, undertaken by the late Mr. Rose, and followed up most ably in several military hospitals, I believe that mercury is still rather more freely employed than it ought to be. I should say, that a moderate swelling and tenderness of the gums, a distinct copper taste in the mouth, and a gentle increase in the secretion of saliva, are the three conditions which we should aim at bringing about; a more violent mercurialisation is not only generally unnecessary, but decidedly injurious. As for the length of time that the salivation should be kept up, it is difficult, also, to lay down any precise rules on this point; sometimes all the specific characters of the ulcer will be removed before it will heal, and sometimes a chancre will heal so rapidly, that you have little opportunity to give mercury before it is well. When the complaint yields in this rapid manner, it is usual to continue the employment of mercury for ten days or a fortnight, and this is done to diminish the risk of secondary symptoms. In other instances, where the sore heals very tardily, perhaps when a bubo is

also present, the disease will not get well for months, though all the specific characters of venereal ulceration may be removed; then, of course, you would not think of continuing mercury till cicatrisation had taken place.

Great judgment is required in the treatment of syphilitic complaints, and it is impossible to give any but general rules for your guidance, so numerous are the peculiarities of different cases, and so remarkable the differences of susceptibility of different constitutions, with regard both to the effects of the disease and the remedies for it.

Gentlemen, I will now make a few remarks on the diet and regimen to be observed during a mercurial course. This subject is important, because if you give a patient mercury, and allow him to continue his usual diet, and to follow his common occupations, you will generally be disappointed in the results of your treatment. If you allow a patient to take wine and a full diet, to walk about the streets, to expose himself to all weathers, and even to ride on horseback, as some are disposed to do, I think you will observe, that secondary symptoms will be more likely to come on, and even affections of the periosteum and bones will be more frequently produced. I always recommend my patients to clothe themselves more warmly than usual, and to confine themselves at home; but there are many who will not submit to this, they say they are obliged to go to their offices, or counting-houses, and that they have no choice; I then say, that, if this be the case, any unfavourable circumstances, which may occur, must be imputed not to my having omitted to give them good advice, but to their not following it.

As mercury produces a quickness of the pulse, and a feverish state of the system, it is advisable not to let the patient have a full meat diet; it is better for him to live on light farinaceous food, such as milk, sago, arrow-root, &c. This practice is consistent with medical science on another account; for, in many venereal cases, there is a good deal of inflammation present; perhaps in the groin there may be severe inflammation, or a similar state of the throat may exist. Under these circumstances, letting the patient have a full diet would be contrary to all the rules, which influence both physicians and surgeons in their treatment of disease in general. When the patient is in so reduced and weak a state, that it is necessary to let him have plenty of animal food, I should say, that mercury can then rarely do him any good. It is especially necessary, also, during a mercurial course, to recommend abstinence from all acid drinks and acid fruits, for mercury has often a tendency to produce diarrhoea, and even mercurial friction will sometimes act more on the bowels than on the salivary glands. When diarrhoea has been induced by the use of mercury, the condition of the patient is much the same as if he had dysentery; a slimy matter is discharged from his bowels, and frequently blood.

Under such circumstances, I need scarcely say, you must discontinue the mercury, for the further administration of it would not only do no good to the venereal complaint, but put the patient's health into a most dangerous state. Let the mercury, then, be left off, and have recourse to opium and rhubarb, or the chalk mixture.

Sometimes mercury has a peculiar effect on the skin, for, in some constitutions, you will find, that it brings out a specific eruption, which is named the *mercurial erythema*, or *eczema*. The cause of this eruptive affection was not at all understood till about five and twenty or thirty years ago, when its nature was made out by some of the practitioners of Dublin. Previously to the date, which I have mentioned, the case was supposed to be a syphilitic eruption; but it is now known that it depends entirely on the action of mercury in particular constitutions. It is generally preceded by an increased heat of the surface, accelerated pulse, difficulty of respiration, and more or less fever. On the first or second day after the feverish attack, the erythematic affection makes its appearance, sometimes bearing a considerable resemblance to urticaria, or nettle-rash, and when it assumes this form, you will always find the disorder very slight; but, in other instances, large red patches appear on the surface, crowded with vesicles, which, uniting altogether, may cover the greater part of the body. After a time they burst and form incrustations in the skin, and the patient, from the extent of surface affected, is really in a very distressing condition. Under wrong treatment this is actually a dangerous complaint; and, in former times, when the disease was supposed to be syphilitic, the quantity of mercury used to be increased, and the patient destroyed.

Former practitioners were confirmed in their suspicions that this was a syphilitic eruption by the fact, that eruptions are rarely the consequence of mercury, but very frequently the consequence of the venereal disease; therefore the cutaneous affection was ascribed to the latter disorder, and treated as such by pushing the mercury in greater quantities, according to old maxims and firmly rooted prejudices. As the mercurial erythema sometimes comes on, when only a small quantity of mercury has been exhibited; it is supposed, that it can occur only when there is a particular idiosyncrasy in the individual: it is asserted that it never takes place, except when the patient has been exposing himself to cold damp air. Here, then, is another reason, why the kind of regimen, which I have recommended, should be attended to. Sometimes the eruption begins on the part where the patient has been rubbing in mercury, as on the thigh or leg; but, in many instances, it comes on, though the mercury has been given only internally; so that the friction is not essential to its production. The treatment consists in fomenting the parts well with a decoction of poppy-heads or chamomile flowers:

you discontinue the mercury, as a matter of course, and administer small doses of antimonial powder and saline purgatives, or castor oil, to which some practitioners are very partial. When the inflammation has abated, and there is merely a discharge from the surface, then sarsaparilla may be given, or bark with diluted sulphuric acid, care being taken that the patient may have a light nutritious diet. The warm bath will also be a means of affording great relief. If the part be excoriated, it will be necessary to apply the zinc ointment.

Mercury acts upon some individuals like a poison: they are seized with palpitations of the heart, tremblings of the limbs, oppression of the breathing, and irregular pulse. When you observe such indisposition in a person employing mercury, you may conclude that this mineral is actually producing a deleterious impression on the system. It was noticed by the late Mr. Pearson, of the Lock Hospital, that every year, when it was the custom to salivate freely, a certain number of individuals in that institution died suddenly during a mercurial course; they were first affected, as I have described, and, on attempting to make the slightest effort, they suddenly dropped down dead. These cases were not taken particular notice of, till Mr. Pearson pointed them out to the profession, and explained the cause of them. He learned, indeed, from experience, that they arose from the deleterious action of mercury on the constitution. The dangerous affection, which I am speaking of, is called the *mercurial erythismus*. I need hardly say, that the treatment consists in suspending the use of mercury altogether, letting the patient be exposed to a pure, cool, dry air, administering tonics, especially sarsaparilla, or, as some practitioners prefer, ammonia in camphor mixture.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE II.

General Remarks on Local Diseases.

GENTLEMEN,—I commence the course by entering at once on the subject of particular diseases. I am aware that the common practice is to occupy the early part of a course on the theory and practice of medicine with preliminary discussions on general pathological subjects. To this I have strong objections. Every man who assumes to himself the office of a teacher, no matter what the fact may be, should presume that his auditors are ignorant of the subject he is about to teach; if he does not he must be unjust to his class. Some of the class must be ignorant of the information he wishes to convey, and he should take it for granted that all are so. To commence with

the consideration of general disease would argue that the whole class was acquainted with the subject in all its bearings, and capable of understanding its principles without any previous illustration. I think this is beginning at the wrong end. My plan is first to teach the facts, and then the general principles and conclusions to which these facts lead. It is of the deepest importance in the study of medicine to be able to form a collection of laws or fixed principles. In your professional career, nothing will give you so much satisfaction as having in your minds a number of established facts and fixed rules to bear on every case which comes under your cognisance. We commonly hear of the uncertainty of medicine and the instability of its practice, it is said to have as many phases as the moon, and as many changes as the tide; but after all, I think this expression is more general among those who know little than among those who know much. Those who have successfully laboured in treasuring up a store of deep and extensive knowledge are firmly convinced, that though some cases are involved in doubt and obscurity, the general certainty of medicine is at present increased far beyond what it was in former times. No man, except one in full and extensive practice, earned by industry and capacity, can be aware of the vast improvements of modern practical medicine, and of the number of lives which are saved by the judicious treatment which the rapidly progressive improvement of medical science has introduced. Medicine is much more certain now than it was in past times. There are two reasons for this, one of which is, that at the present period diagnosis, the guide and master key to sound treatment, is more certain. Here, gentlemen, is a great source of certainty in the practice of medicine. You will find in the course of a few years, that the old saying of "doctors differ," will become less frequently applicable, because as the education and acquirements of medical men become more extended, diagnosis will be reduced to fixed rules and difference of opinion will be very seldom observed. A vast number of local diseases, formerly wrapt in obscurity, are now detected with the most unerring certainty, and this certainty of diagnosis must bear on fixed principles of treatment and similarity of practice. Another vast source of increased certainty is the fact, now extensively established, that the element of a great number of diseases is the same. This is an important law, because the deduction from it is, that the principles of treatment are the same in these cases. The principles of treatment in a case of hydrocephalus and in a case of vomiting from gastritis may be, and often are, completely identical, because in many cases both are reducible to a common action. In the one case we have to deal with inflammatory action in the stomach, in the other we have to treat an inflammation of the membranes of the brain. The principle in

both cases is to deplete the suffering organ and to diminish or remove every thing that keeps up irritation. Pathological anatomy, too, has effected a vast deal for medicine by the improvements in diagnosis which it has introduced, and by reducing to one class a vast number of affections formerly supposed to be unanalogous and distinct.

Before I commence entering on the consideration of the pathology and treatment of diseases of the digestive system, it is necessary that I should mention another peculiarity of the mode of teaching the theory and practice of medicine adopted in this school. The ordinary way of lecturing medicine in the schools is this: the teacher begins by going over at great length the whole subject of fevers, and then proceeds to the consideration of the signs, symptoms, and treatment of local diseases. We reverse this mode here; we begin by teaching the pathology and treatment of local diseases, or affections of particular organs, and having studied these with care and attention, we then proceed to the consideration of fevers. In point of fact, we are thoroughly impressed with the truth of this splendid conclusion in medicine, that local diseases may be considered, as it were, the alphabet of fevers, and that to have a distinct and accurate conception of the whole subject of fever, it is essentially necessary that we should be acquainted with all kinds of local disease. To commence with a class which the teacher presumes, or should presume to be ignorant of the phenomena of local diseases, unacquainted with the rules on which their diagnosis depends, and unacquainted with the principles which should regulate their treatment; to begin with such a class by entering at once on the subject of fever would in my opinion be extremely wrong. You will read in books and hear teachers speak of bilious fevers, of nervous fevers, of catarrhal fevers, of gastric fevers, and of simple fevers. These expressions are founded on the fact of the complication or non-complication of fever with local disease in various parts of the system. If simple fever was the rule, and its complication the exception, then, indeed, there would be some reason for pursuing the ordinary track of medical instruction, and we might commence by teaching the subject of fever independent of local inflammation. But the truth is, that fever in the simple form is the exception, and its complication the rule, and that to have a correct idea of fever, in the general acceptance of the term, we must previously possess an intimate knowledge of the affections of particular organs. The progress of medicine has established by the most unquestionable evidence, that simple fever is a matter of extremely rare occurrence, so rare, in fact, that you might pass through the practice of a fever hospital for years without meeting with a single case which you could say was, through its whole course, a case of pure, essential fever. Sooner or later its character is changed, and the complication

with visceral disease comes on; you may take this with you as a well-proved fact. You will have at some period a complication with local disease in the head, or local disease in the chest, or in the belly, or in the circulating system, or perhaps all the great viscera in the body will be simultaneously affected. My experience on this point, after having attended the fever wards of the Meath Hospital many years, is this, that among all the cases which were admitted under such circumstances, there were very few indeed in which I could not say that the patient had something more than fever. Many were admitted who presented no indication of disease in the head, chest, or digestive tube; all that could be said of them at the period of their admission was, that they had fever; but my experience of them is that in a vast majority, there was during their progress unequivocal evidence of the supervention of visceral disease. I do not go as far as the disciples of Broussais have gone, nor do I mean to say, that all fevers are symptomatic; all I assert is that at some period, most fevers are complicated with local disease. I admit that there is a vast number of symptomatic fevers, but I believe there are two which are essentially simple, typhus and intermittent. The progress of medicine has shown that these may exist in the simple form, and that their complications may be secondary; this I believe to be the fact, but the almost invariable liability to complication is a point of the highest importance. We scarcely ever see typhus accompanied by symptoms of local disease; and with respect to intermittent, in ninety-nine cases out of a hundred, visceral disease of the head, or chest, or belly may, and will, supervene.

Another great fact bearing on this subject, and which pathological anatomy has established beyond the possibility of a doubt, is, that in the great majority of cases having a fatal termination, death is caused by disease of some particular organ or organs. The old notion of the cause of death was, that the patient died of debility or exhaustion. In cholera, in tetanus, in hydrophobia, we cannot, to be sure demonstrate any appreciable lesion of structure, and we may say, if we like, that the patient died of debility; but this does not hold good in cases of fever, for on dissection you will generally find disease sufficient to account for death, even though there had been no fever at all. From these circumstances it follows that in the management of fevers, the attention of the physician must be directed to the local affections, or, at all events, that to understand fever well and treat it successfully, he must be acquainted with the nature and treatment of every form of visceral disease. It will be sufficient for me to call your attention to this fact that *there is not a single acute local disease which may not occur during the progress of a fever*. This is a broad and general proposition. If you look to the nervous system you will find in patients

who have died of fever, traces of lesion in almost every part of it, inflammation or congestion in the cerebrum, in the cerebellum, and in the spinal cord. If you go to the respiratory system, you will see all kinds of shades, and varieties of inflammatory action, thickening and ulceration of the bronchial membrane, hepatisation, congestion, and destruction of the parenchymatous tissue, effusions of lymph, serum, or pus into the pleural cavities. As you proceed in your examination you will discover new lesions; you may see the whole lung filled with lately formed tubercular matter, you will meet with the destructive ravages of phthisis. You will find the pulmonary tissue converted into a dark and foetid mass by gangrene. You may see carditis, hypertrophy, inflammation of the external or internal coverings of the heart, inflammation of the lining membrane of the arteries, phlebitis (a common occurrence in typhus fever), and passing on to the lymphatic system, you will often find evident traces of inflammation in its glands and vessels, an occurrence which I shall be able to demonstrate to you when treating on the subject of gastric fever. If we go to the digestive system we find that disease has here taken a wider range; congestions and ulcerations of the stomach and intestines, morbid states of the liver, congestion and inflammation of the spleen or kidneys evidence the fatal extent of local inflammation. I think I might safely challenge any one to point out any one single organ which may not become diseased during the progress of a typhus fever. I do not wish you to suppose that typhus is a symptomatic affection. I think we may define it, in general terms, as a diseased state of the whole system, in which various local diseases arise, modify the character of the original complaint, give it an additional intensity, and are generally the cause of death. Go round the wards of an hospital during the prevalence of an epidemic fever, examine every patient in succession, and bring this principle to the test. You will see one labouring under the morbid excitement of high delirium; his face injected, his eyes sparkling, his carotids throbbing with intensity. Come next day, and you will find him in a state of profound coma, perfectly insensible to every thing around him:—two or three days afterwards he is dead. You follow his body to the dissecting room and open his brain; unequivocal marks of excessive congestion, inflammation of the substance of the brain or of its membranes sufficiently indicate the cause of the fatal termination. Here is a case of inflammation of the brain; you find another with cold skin, his face of a dirty hue faintly tinged with red, his breathing quick and hurried, and the spitting-vessel by his bedside filled with adhesive mucus tinged with blood; you percuss his chest and find dullness over the whole surface of one lung; you apply the stethoscope and discover intense bronchitis, hepatisation, or suppurative pneumonia. Farther on you see another in a state of deep pro-

stration, with a sunken countenance, constant hiccup, and low delirium. Take down his bed-clothes, and you find his belly swelled, tympanitic, and tender on pressure; then his tongue, lips, and gums, are parched and encrusted with dusky sordes; his thirst is insatiable; he vomits, and has an emaciating diarrhoea. After death you find traces of an extensive and fatal gastro-enteritis; in others you will find exemplified the very climax of inflammation, and all the three great cavities are simultaneously affected.

But these, you will say, are cases in which the complications are evident, and where an ordinary knowledge of the phenomena of local disease will be quite a sufficient guide. Well, here is another case. You will meet with instances of fever without any apparent local symptoms, where the patient lies in what you would consider a quiet state, and free from danger: nothing seems to be the matter with him, except that he is very weak; he perhaps does not sleep at night, and his tongue is a little foul; he complains, in fact, of nothing but weakness and some thirst, and you think his fever is going on very well. Some morning or other, on coming to the hospital, you are astonished to see the change which has been wrought in him since the day before; his countenance is altered, his pulse can hardly be felt, and life is fast ebbing away. You ask the nurse about him, and she tells you that, during the night, he suddenly complained of violent pain in his belly. On examining him, you find distinct evidence of intense peritonitis, and, after death, dissection reveals the existence of a perforating ulcer of the intestines, of which there was apparently no sign during life, except fever and the unexpected occurrence of peritonitis. The frequency of the complication of local disease with fever, its insidious latency, and the fact, that death, in the majority of fever cases, is caused by visceral inflammations, all clearly point out the necessity of being intimately acquainted with every modification of local disease before you proceed to the study of fevers.

Gentlemen, I commence with the digestive system. I am anxious to do this for several reasons, but for none more than this—that to the improvements made in the pathology of the digestive system we owe much of the rapid advancement of modern practical medicine. Before our time the pathology of the digestive system was very little known, and if not quite a *terra incognita* in medicine, there existed respecting it a great deal of misconception. The schools were deeply tinctured with the doctrines of the Humoralists and the Brownists; and this had the effect of giving rise to irrational theories and false notions of the true state of the system in disease. The humoral pathologists, who sought for disease in an alteration of the fluids alone, neglected the study of visceral lesions; and when they turned their attention to the digestive system, they only considered it, its secretions,

and not its actual condition or the state of its sympathies. The liver, with them, was an organ of the highest importance, and the secretion of bile claimed a vast share of their attention. To it they gave a paramount influence, and to an alteration in its quantity and quality they attributed most of the changes which occur, not only in the digestive tube, but also in the whole system; and hence the great object of their practice was to attempt to restore its healthy condition, convinced that if this were once accomplished every thing would go on favourably. From this, too, arose the purgative plan of treatment in various forms of intestinal disease, a plan too often rashly pursued, even where there was unequivocal proof of inflammation in the digestive tube. Their sole purpose was to evacuate sordes, to produce a flow of healthy bile, and to eliminate depraved secretions; and they did this without possessing any knowledge of local inflammation, or of the effects of disease of the digestive system on other organs. The followers of Brown, on the other hand, only admitted disease of the digestive system in a state of intense, manifest violence, as for instance, ileus, or violent enteritis; but, in the great majority of cases, they did not recognise intestinal inflammations, because their prominent symptom was prostration, or, to use their own terms, an asthenic condition of the whole system. They saw nothing but prostration; they prescribed for nothing but debility; they gave wine instead of iced water; ordered bark instead of local depletion. They exasperated the disease by stimulants; and then, thinking they had not gone far enough, they heightened the stimulant and doubled the debility.

Another cause of the low state of pathology in former times was the general neglect of dissection. The fact is, that in fever there were no post mortem examinations made, until very lately. Morgagni, who did so much for pathological anatomy on almost every other subject, did little for fever, because he was afraid to dissect the bodies of persons who had died of a contagious disease. This was the idea which prevailed among the older pathologists; and hence this source of knowledge was avoided, and for many successive centuries the state of the viscera in fever was a matter of speculation, doubt, and uncertainty. Even at the present day it is only done by the ardent pathologist, who cares not about filth and stench, and who had rather encounter the miasm of contagion than remain in the mists of error. Nothing is more common, I regret to say, even at the present time, than this:—A person says he has dissected cases of fever, and when asked whether he had examined the intestinal canal, he says that the intestines appeared healthy, but he did not make any particular inspection of them; he only opened the belly, and, finding no trace of inflammation in the peritoneum, he went no farther. Now nothing can be more useless than such an examination. If we compare the information

afforded by an inspection of the serous membranes of the three great cavities, we shall find that the least is given by an examination of that of the abdomen. Disease of the substance of the brain is rare without affections of its investing membrane, disease of the substance of the lung is exceedingly rare without the occurrence of disease of the pleura, but you may have most extensive and fatal disease of the intestinal canal without the slightest lesion of the peritoneum. In this point, therefore, it differs from the pleura, and from the arachnoid membrane. The fact of the rarity of disease of the peritoneum in cases of disease affecting the parts beneath, was noticed by Dr. Graves and myself, in our report of the Meath Hospital, and also by Mr. Annesley, in his account of the diseases of India. You will see cases of hepatic abscess, which present a distinct tumour externally, and where you can detect a perceptible fluctuation; and yet, if you examine these cases after death, you may not find any adhesions of the peritoneum, even in the situation of the abscess. You will find the mucous and muscular coats of the colon extensively destroyed, you will see the stomach all but perforated, you will meet with cases where the whole ileum is one extensive sheet of ulcerations, with no disease in the adjacent peritoneum.

In entering on the consideration of diseases of the digestive system, we shall begin first with the mucous expansion of the stomach and intestines, and then proceed to the affections of the solid viscera connected with them. The mucous surface of the stomach and intestines is of enormous extent and extraordinary sensibility, possessed of innumerable and powerful sympathies; its influence is felt by almost every organ in the body, formed for receiving and elaborating every thing destined for nutrition; its conditions, both in health and disease, are entitled to the deepest and most attentive consideration. To facilitate the study of its affections, and for the sake of some practical arrangement, we shall divide its diseases into five classes, beginning with the cesophagus, or that portion of the digestive tube which is above the diaphragm, and then proceeding to the stomach, duodenum, ilium, colon, and rectum. But in order to give you a clear idea of diseases of the intestinal canal, I shall commence with diseases of the stomach; because, if you consider the whole range of animal life, you will find that its functions, are the most important, the stomach constituting, as it were, the source and fountain of life, which is nutrition, and giving by its existence a character to all the upper classes of animals. No organ possesses such remarkable sympathies as the stomach, whether we look upon them as sympathies of organic or of animal life, none possesses such remarkable power and influence in modifying the conditions of every part of the system. But, putting aside physiological reasons, let us come to practical matters. The success of

almost every form of medical treatment, all the advantages to be derived from the administration of internal medicine depend upon the stomach; in fact, in whatever point of view we consider it, we must look upon a knowledge of the state of the stomach as the great key to sound and successful practice.

It is a most useful reflection to consider the extraordinary frequency of disease in some portion of the digestive tube. It is now admitted by every person possessed of experience in the causes of mortality, that more human beings die with acute or chronic diseases of the digestive tube than with diseases of any other part of the system. This has been established by numerous investigations, and is admitted by the best pathologists; and, indeed, I think it can be easily accounted for, when we call to mind how many persons die of some form of fever or other, when we look to the ravages of remittent and yellow fever, to the hundreds of thousands who annually perish by the various classes of fevers. Now in almost every one of these cases, disease of the digestive system forms one of the most prominent pathological characters. Recollect, besides, all that die of dysentery, whether sporadic or simple, and here is inflammation of the colon; see, too, how many die with diarrhoea,—here, too, there is intestinal disease; remember how many die of the malignant intermittent of the West Indies, in which unequivocal proofs of disease of the stomach and intestines have been found. Observe what a close connexion there is between *tabes mesenterica*, and inflammation of the mucous membrane and surface of the intestines; think what a vast number of persons fall victims to the harassing effects of constipation and dyspepsia; and recollect that there is a host of diseases in which the train of morbid phenomena commences in the digestive system, and then exhibits itself by functional alteration or organic disease of other parts.

Gentlemen, we recognise the presence of disease in the digestive tube, first by the local phenomena and the lesion of the digestive function, and next by the sympathetic relations of other parts, by the sympathies of the respiratory system, of the circulation of the skin and of the nervous system. I shall enumerate the local phenomena and functional lesions: vomiting, anorexia, thirst, jaundice, pain, tenderness on pressure, tympanitis, changes in the character and quality of the discharges, constipation. Here are a set of functional lesions and local phenomena; let us now consider the sympathetic relations; these are fever, heat of skin, suppression of the cutaneous secretion, suppression of the secretion of urine, morbid states of the tongue and pulse, pains in the chest and cough, hurried breathing, and palpitations of the heart. In the next place, we may have prostration of strength, delirium, coma, convulsions, tetanic spasms, and other symptoms of functional disease of the brain;

these are all sympathies of relation. Now, in the first place, I have to remark, that there is a great deal of variety in the combination of these symptoms. On what does this depend? on a variety of circumstances; sometimes on the intensity or extent of the inflammation; sometimes on the situation of the disease; sometimes on the complication of the affection; sometimes on the various modes and degrees of susceptibility of the individual. All these causes tend to produce a great variety in the disease, and an extensive modification of the sympathetic relations. For instance, in some cases, inflammation of the stomach and intestines is so slight that the patient is not prevented from going about and pursuing his ordinary avocations; in others, on the contrary, the patients are struck down at once by the violence of the disease, and are carried off by the fever which accompanies it before the inflammation is completely developed. It varies also according to situation; there is a difference between gastritis and dysentery, in the former we have an inactive state of the great intestine, and consequent constipation in the latter, the colon is thrown into violent action, and there are frequent dejections. Disease of the duodenum is attended with a very remarkable peculiarity, being very frequently complicated with jaundice; here is a modification produced by situation. Again, inflammation of the ileum is attended with a very curious peculiarity, namely, the absence of pain. The patient states, that he feels unwell, he has obscure symptoms of intestinal disease, but it is neither dysentery nor gastritis; you investigate it with care and find that the ileum is in a state of inflammation. Yet the patient does not complain of any pain, and this is another peculiarity depending on situation.

But in considering the differences which depend upon intensity, extent, and situation of disease of the intestinal canal, we must not omit those which depend upon tissue. If disease be confined to the mucous membrane of the intestines alone, we may have an extremely diffused and extensive inflammation sufficient to destroy life, without any pain being complained of by the patient, it is a painless though fatal disease. Recollect this, extensive and fatal inflammation without pain. In former times the ideas of pain and inflammation were inseparable. Thanks to the light which pathology has shed upon modern medical science we are now acquainted with this seeming anomaly, and can conceive the existence of extensive disease of mucous surfaces unaccompanied by pain. But let the inflammation seize on the muscular tissue, the character of the disease is instantly changed, and the pain is dreadful. Here is a case in which difference of tissue is to be taken into consideration.

The phenomena and sympathetic relations of intestinal disease may vary also according to its complication, and here we come to in-

investigate one of the most beautiful laws of the human economy, namely, that the more complicated a disease is the more latent will be any local lesion. This is a point that should never be forgotten. For instance, enteritis by itself is much more easily recognised than when complicated with pneumonia, or with irritation of the brain, and gastritis is but too often completely masked by being combined with irritation of the bronchial mucous membrane. Lastly, we have the varieties which depend on different degrees of susceptibility. In one person we may have only slight cerebral irritation, in another high excitement, in a third delirium and extraordinary convulsions. The variety, then, in the modifications of disease, and the combination of sympathies is very great, and is referable to the extent and the intensity of the inflammation, difference of situation, complication of disease, difference of tissue, and different degrees of susceptibility. I shall give examples of these at my next lecture, and then proceed to the pathology and treatment of gastritis.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE VIII.

On the Anatomy and Diseases of the Bladder and Urethra.

GENTLEMEN,—In supporting the opinions of Sir C. Bell, Mr. Shaw, and others, with respect to the urethra being elastic, in opposition to those maintained by Mr. Hunter, Sir E. Home, Mr. Wilson, and those anatomists who have considered it to be muscular, I am forced to confess my dissatisfaction at the explanation they give of the manner, in which the various changes take place, constituting disease. It appears to me, and I admit my great liability to err in understanding the opinions of others, that these changes cannot occur from *inorganic elasticity* only, or the same kind of property which is found in Indian rubber; and that it is necessary something should be added, to enable us clearly to understand the subject matter before us. I am led therefore to make a distinction between the common elasticity residing in a spring, or in Indian rubber, and the *vital elasticity* which exists in all the elastic parts of the human body, and by means of which the various changes that take place may be more easily comprehended. The first principal change to be noticed, and which bears particularly on this point, is the state of contraction of the canal impeding or even preventing the passage of the urine, and which has been divided into *spasmodic* and *permanent*.

Mr. Hunter assuming the fact, that the

urethra was muscular, supposed that the first derangement leading to, or causing contraction, arose from a spasmodic action, producing a degree of contraction beyond the natural, and which he called a spasm, and the complaint a spasmodic stricture.

When the part, thus contracted, became incapable of falling back into a state of complete relaxation, and the canal remained always narrower at that part, we considered it to be both a permanent and spasmodic stricture. So far permanent that it is always narrower than the rest of the canal, and so far spasmodic that it is liable to contract occasionally in a still greater degree, and he supposed both the spasmodic and permanent state to be caused by a contraction of the transverse fibres of the membrane which forms the canal.

Sir E. Home, in consequence of the microscopical observations of M. Bauer, was led to take nearly a similar, although, in some respects, a different view. He supposes the urethra to be composed of two parts; a fine internal membrane, which is not fibrous, but which, when collapsed, is thrown into longitudinal folds, and an external muscular one, composed of very short fasciculi of longitudinal fibres, which appear to be interwoven together and to be connected by their origins and insertions with each other. The fasciculi being united to each other by an elastic substance of the consistence of mucus.

"A spasmodic stricture," he says, "is in reality a contraction of a small portion of the longitudinal muscular fibres, while the rest are relaxed, and as this may take place, either all round, or upon any side, it explains what is met with in practice, and which could not before be satisfactorily accounted for; the mark or impression of a stricture sometimes forming a circular depression upon the bougie, at others only on one side.

"A permanent stricture is that contraction of the canal, which takes place in consequence of coagulable lymph being exuded between the fasciculi of muscular fibres, and upon the internal membrane, in different quantities according to circumstances."

Sir Charles Bell, in denying the muscularity of the urethra, has however recourse to the agency of the neighbouring muscles, in order to explain the nature of the obstruction which has taken place, and considers that the spasm is not in the stricture itself, but in the muscles surrounding it and the urethra.

Since the period at which these gentlemen wrote, a change has gradually taken place in the opinions of surgeons on these points, if not in their language; and although the words spasm and spasmodic are constantly used to express a particular state of parts, they are not intended in general to convey a distinct idea of muscular contraction, with which understanding the sense is immediately obvious, but without which it is as confused as it is indefinite.

The only case of pure spasmodic action,

which has come under my observation, occurred in a gentleman, who has come to my house twice, in the course of several years, declaring he could not make his water, and desiring to have the catheter passed, which was each time done without the least difficulty. The first time he came he was quite aware of his situation; said it arose from anxiety of mind relating to family affairs, and that the passage of the instrument would immediately and effectually relieve him. If there was any obstacle, and I was by no means certain of there being any beyond a hesitation, it was at the commencement of the membranous part of the urethra, and arising, I suppose, from a spasmodic contraction of the compressor urethrae of Mr. Wilson, of which I have given a detailed description. As this gentleman suffered no kind of inconvenience at any other time, I am induced to believe, that there was no particular irritation in the urethra, and that it was, as the cause is unknown, what may be called accidentally spasmodic. I have read of a lawyer, a gentleman, but I do not recollect where I saw it, who often suffered in this way when engaged long in court in a difficult case, and who was always relieved in a similar manner; but here I should say it is more than probable the individual was labouring under some slight permanent irritation in the urethra, or that it was at least in an excitable state at some one part near the bulb. A healthy man, suffering from anxiety and alarm, often feels a desire to pass his water, which he cannot at all times restrain, and it flows whether he will or not; but if he has the power of restraining it for hours, then, indeed, the powerful contractions of the compressor urethrae may bring on irritation in the part, and spasm of the muscle; but this is the result of its own irregular and long-continued action, inducing inflammation and disease, and is of exceedingly rare occurrence; still it is not an instance of pure spasm, like the case I have related, in which the incapability was preceded by no uneasiness until the attempt at micturition was made.

The more common cases, which are usually considered spasmodic, are those of young men, who, when suffering from gleet or gonorrhoea imperfectly or only partially cured, are tempted to commit an excess in wine or punch. After sitting some time, they feel a desire to make water, which they repress, or perhaps indulge with some difficulty, but which increases, and is soon found to be irrelievable without assistance. The greater the effort, the more determined the straining, the greater is the agony, and the sufferer, with despair depicted in his countenance, entreats relief. According to the received rules of surgery, the proper practice in such cases is, to relieve, first, the spasm by sending him to bed, by fomenting the parts with hot anodyne fluids, and by giving him a dose of the pulv. ipecacuanhae comp., under the influence of which, in the course of a few hours of misery, it is not im-

probable but the urine may begin to flow. You then purge him with salts and senna, and it is likely that his urine will flow in a full stream, when the evil subsides or entirely goes away. This is the practice you are generally called upon to subscribe to, but I always declare it to be bad, and never to be followed unless you cannot do anything else. I was taught better many years ago by a Scotch friend of mine, a young man although an old soldier, who, after a debauch of this kind, which lasted half the night, found he could not make water when he awoke in the morning from his feverish dreams. He sent for me, begging I would bring a catheter with me. When I arrived, I proposed a warm bath, an opiate draught, enema, &c., his answer was peremptory enough,—“Damn your draughts, Doctor, pass the catheter, I have had it before.” As remonstrance was useless, I passed the instrument with some little difficulty, and drew off his water, upon which he jumped into bed, saying,—“God bless you, Doctor, but damn your physic.” In the afternoon when I saw him he was nearly free from inconvenience. Since that time I have always made it a rule to try and pass a catheter in every case of retention of urine. If it passes, so much the better; if it does not, the patient submits more cheerfully to the longer course of treatment. I presume I need not caution you against using force, which in such cases is unnecessary. It is by lightness of hand, and dexterity in the use of your instrument, that you gain your point. If you fail, inject a large quantity or repeated quantities of hot water into the rectum, and when the bowel is clear, and the hot water has acted as a bath to the neck of the bladder, inject from 50 to 60 drops of laudanum in 2 ounces of warm water. This will remain, and by its sedative qualities often gives effectual relief. Leeches, bleeding, the warm bath, Dover's powder, or calomel, James's powder and opium will assist, and by a repetition of these means, even in the worst of cases a relaxation or subsidence of irritation will take place, and the water will begin to flow.

These are called cases of spasm, I call them cases of inflammation, and which induces a want of consent, as Sir C. Bell expresses it, between the muscles of the parts, so that when the bladder acts, the muscles surrounding the urethra will not act by yielding and dilating as they ought to do, but remain, or become more permanently contracted; the urine is forced against the inflamed and contracted part of the urethra, and by its irritation increases the mischief. When the water is drawn off the desire to pass it is removed, and the greatest irritation on the inflamed or irritable part of the urethra is taken away. Experience has also long pointed out to us, that when the patient can pass his water, the complaint is yielding, and the object is to get it to flow, and mechanical means in these cases

will always do more than general ones, although I by no means deny their use as auxiliaries. If the case be more advanced, and the catheter will not pass, or you are at a distance from home and have not one small enough at hand, take a common bougie, and soften the point by dipping it into warm water, but which is not warm enough to melt the material of which it is composed, pass it down to the obstruction, and press it steadily, but not painfully so, against it, and let it remain for several minutes. It will often be found to pass on, or the patient will find on withdrawing it that he can pass his water in small quantities. The mischief here is a slight degree of inflammation, aggravated by cold or intemperance, but without any permanent alteration in the structure of the urethra, yet I do not believe it is caused by spasm. Let us be more precise. The difference between a spasmodic and a permanent stricture is this:—The *spasmodic* is supposed to depend on some muscular contraction of a temporary nature in, or exterior to, the canal itself. The *permanent* upon some positive alteration of structure of the wall of the canal, which thickens, and at the same time deprives it of its capability of being dilated, with the same facility and to the same extent as in a state of health. This alteration of stricture is produced by inflammation, although it is difficult to account for the various appearances which these altered parts assume from it alone. If the theory laid down by Mr. Hunter could be maintained, and the circular or the longitudinal muscular fibres described by Sir E. Home and Mr. Bauer could be satisfactorily demonstrated to be muscular, nothing could be more simple than the manner in which a stricture might be formed, and it is this simplicity which has won the belief of so many surgeons in that which they could not see, but which from its appearing so very satisfactory, they even wished to be the case. A temporary or spasmodic contraction of a muscular fibre is a very intelligible thing, and that after a time a continuation of this state should bring on inflammation and thickening is consistent with our general knowledge; and it is only to be regretted that it should not be an established fact, that a stricture is formed in this manner. A permanent stricture, which has offered during life considerable resistance to the passage of an instrument, may be found after death to have been formed by a mere line of irregular thickening, extending only for a third of an inch in an oblique direction along the canal. In most instances, it is more or less circular, generally affecting the under rather than the upper part. The best case of this kind I ever saw was in a journeyman baker, who came to me many years ago with a stricture, not exactly at the orifice of the urethra, but at so short a distance from it, that it could be distinctly seen passing across the canal, like a thin fold of membrane. The opening for the passage of the urine was on

the right side, and would not admit the end of a common probe, although a small one for the lachrymal duct could be passed into it. The temptation to divide this was irresistible; and after having dilated the opening a little, I cut through the septum, which resembled an opaque membrane drawn across the canal with a blunt pointed iris knife, and removed the disease, which appeared to be formed from the inner mucous membrane alone. The successful result of this case induced me to adopt a similar method of treatment in a stricture of the rectum about two inches from the verge of the anus, which occurred to me some time afterwards. The patient, a gentleman from Jamaica, came to me, able to pass only a urethra bougie No. 12, and which he had been doing, under the direction of his medical attendant, for some time, because a larger one could not be introduced. This situation was distressing, and demanding almost imperatively that some greater effort should be made for his relief. The very point of the fore finger ascertained most distinctly, that the opening was in the middle of a septum, extending in every direction from the circumference, and I did not hesitate, after several examinations, to introduce a guarded and blunt pointed bistoury through the opening, so that the blunt end just passed beyond it. I then turned the part of the edge near the blunt end, which was left unguarded, in four different directions in succession, and divided by each cut a small portion of the septum, when a bougie of twice the former size passed without difficulty. I was obliged to repeat this operation twice at proper intervals, when the largest sized rectum bougie in common use passed easily, and the gentleman returned to Jamaica cured, although with the direction to use the bougie from time to time. These two cases, in addition to others less observable or marked, but nearly as conclusive, satisfied me that a mucous membrane was capable of producing a particular septum-like contraction in its proper canal, without the participation of its muscular or of its elastic coat; for I cannot believe that the muscular coat of the bowel formed a part of the stricture in one instance, more than the elastic coat of the urethra did in the other; and it certainly did not appear to be implicated in the former. Repeated dissections have, however, proved to me, that in permanent stricture, the external or elastic coat is almost always more or less implicated; and that the degree of implication is usually in proportion to the obstinacy of the stricture. Thus, for example, a stricture two inches from the orifice will be the most obstinate and the most difficult of cure, in which the corpus spongiosum is found to be hard and unyielding to the touch. It is only to be exceeded in obstinacy of resistance and difficulty of cure, when this part is smaller and harder than natural, when it has, in fact, become impervious, or nearly so, to the blood by which, in its erectile state it, ought to be distended. A stricture of this

kind, which is without the reach of any external muscular fibres, is said to be also spasmodically affected, and thus a permanent stricture is also said to be spasmodic as well as permanent. I do not, however, think that spasm, properly speaking, has any influence in such cases, and more particularly unless muscular or contractile fibres of the wall of the canal are admitted. A gentleman presents himself with a stricture at two, three, four, or more inches in the canal, which, at the orifice, is capable of admitting a No. 13 or 14 solid bougie, but the stricture will only allow a No. 6 to pass. You dilate this slowly, until a No. 10 or 11 will pass easily, when, anxious to have his case completed, your patient presses you to increase the size, and yielding to his solicitations, or tempted by your own desires, you pass over the intermediate number, and take the 13 or 14 at once; you will often be able to succeed, with little uneasiness at the moment, but your patient, on wanting to make water, finds he cannot do it, he strains, but it comes only by drops. The desire increases to misery, and he sends for you. Now, what would you do? Theory teaches, put him in the warm bath, give him an opiate, bleed him if necessary, for the case is one of inflammation; but practical surgery says, do nothing of the kind, but take a small elastic gum bougie without a stilet, and draw off the water. Your patient will be immediately relieved, will wish you good night, if he is a wise man, and go to sleep; when he wakes, he will make his water without your assistance; but when you try to pass a bougie for him some six or eight days afterwards, you will find yourself very much where you were when you began, that is, able to introduce only a No. 6. The part has contracted as much as ever, although perhaps it may be more readily dilated. The necessity for great gentleness in all these cases cannot be more forcibly exemplified.

An instance of this kind occurred to me this week, in a very particular case, which I will relate. The gentleman, a half-pay officer, had been a patient of mine some fifteen years ago, when I cured him of a fistula in ano, and of strictures of the urethra. When we parted, I recommended him to pass a bougie from time to time to prevent their return. This advice he neglected, and some two years ago, finding great difficulty in micturition, he applied to a practitioner of eminence in the Netherlands, who, after a long continued trial, passed a sound for ten inches, and said it was in the bladder; but as the symptoms did not diminish, he fixed a gum elastic catheter in the urethra, and kept one there, changing it occasionally, for fourteen months. The patient did not discover that the water did not pass through it, but came by the side of it for many months; and as the symptoms still continued unabated the surgeon took to injecting warm water, and at last injected the rectum so full, that the patient discharged at once a pint

or more per anum before his face. He now thought it time to give up the catheter, and some months afterwards came to London. It was quite clear, after due examination, that the catheter had passed behind the prostate, although the opening into the rectum had closed. The false passage began just anterior to the membranous part of the urethra, and the natural opening, or canal of the urethra, was so small, and the false passage so large, that every thing took that road, and it was only after a great many trials, and after great attention and management, that a small gum elastic catheter could be got into the bladder. After a few days, this was increased in size, and as he was an old performer, he got others made to suit himself, and went on to No. 14. I now advised him not to increase the size, as some urine came through some old fistulae in perineo, but to pass a smaller silver catheter every other day. He suffered no uneasiness from his No. 14, and used to walk the streets and dine at his club with it in the bladder, and without thinking about it. I pointed him out in Piccadilly, to Dr. Fergusson, of Windsor, who happened to be in the carriage with me one day, and he would scarcely believe it. Well, one Wednesday morning he left out his gum catheter, having his silver one ready, which he tried on the Thursday, but to his great surprise the attempt to pass it gave him excessive pain, and it would not proceed even for half an inch. He came to me directly, saying a horrible spasm had seized him, and nothing would pass. I tried a No. 8, and found it would not go half an inch without great pain, and a smaller one was perfectly stopped at three inches, by a spot which had heretofore shown little sign of disease.

In these cases there was really no spasm. The external elastic structure of the urethra was dilated, perhaps beyond what it could bear, and inflammation ensued. None, however, took place, as long as the dilatation was continued, but as soon as the pressure caused by it was removed, inflammation ensued, the sensibility became greatly augmented, and the part contracted by its vital elasticity; by which I understand something like that property possessed by the middle coat of an artery, a property very observable during life, but which is lost after death. These cases may be called instances of spasm affecting permanent strictures, but where the urethra is really diseased, and the outer elastic structure is implicated, it is not necessary to have recourse to the idea of spasm of any muscular structure external to it, for an explication of the mischief.

That a muscular coat or wall of a canal, can, when it exists, exert an especial and long continued, although transitory influence on the canal, I have had opportunities of seeing; and in one case in the oesophagus, in a very remarkable manner. The patient, a young lady, had suffered for years from repeated difficulties in swallowing, which at last became positive obstructions, preventing the passage of

either solids or fluids for days. The obstruction usually yielded almost suddenly, and the lady could then swallow liquids and small masses of food. A good sized œsophagus bougie could then be passed with little sense of opposition, although the stricture was distinct, when swallowing was impossible, about an inch below the situation of the cricoid cartilage, and no bougie could then be forced through it, although frequently attempted by several very able men. As the complaint continued, the impossibility of passing a particle of food became more frequent, and lasted for eighteen, twenty, and six and twenty days together, so that at last the lady became quite exhausted, and died from inanition, in the full possession of her senses, and with a Christian resignation of so perfect and admirable a nature, that it was impossible to look upon it but with the strongest feelings of gratitude to God for his goodness. On examination I found the œsophagus externally of its natural appearance, without the slightest sign of constriction. When slit open, it appeared of its usual thickness, and without any deviation from its ordinary state, with respect to the appearance of the muscular layers; but on the inside, and adhering firmly to the mucous coat, there was a false membrane, the upper edge of which appeared to have been separated, in consequence of the repeated application of the bougie, and a little turned inwards, so as to fill up, in part, the canal through which, however, any common sized bougie could after death be passed. The mucous membrane from this part onward to the stomach, which was not allowed to be examined, seemed to have lost its normal character, and to have taken on that of a serous one, on which a false membrane readily forms, but which rarely takes place on a mucous one, unless some great alteration has previously taken place in it. The difficulty which existed at all times, for several months, arose from this false membrane, which could be peeled off, and resembled chamois leather; whilst the permanent and insurmountable obstacle, which often existed for three weeks at a time, must have arisen in part, I conceive, from muscular contraction, although no trace of permanent stricture was observable after death.

I am led to infer from a due consideration of these and many other similar cases that the canal of the urethra might be perfectly closed for a considerable length of time by a spasmodic contraction of its muscular coat, of a transitory kind, provided such muscular coat were believed to exist; but as such belief is not commonly entertained, I prefer supposing that the obstruction takes place from inflammation of the internal mucous membrane, which alters its attractions and properties, assisted by an undue contraction of the elastic and outer wall of the canal, dependent on its vital elasticity or contractability. I believe this to be the case in all instances except those alluded to in the commencement of these ob-

servations, in which an undue action of the compressor urethræ muscle alone may have produced the effect.

When the outer elastic wall is only excited to contract, but is not thickened, the case is then one of those usually called a spasmodic or dilatable stricture; when the elastic coat is altered in structure it is then called a permanent stricture; and these may be divided into two or more kinds. Those which are completely curable, and those which are not; so that in whatever manner the latter are temporarily removed, they are prone to return, and will return without care is taken to prevent it.

The slightest alteration is a mere thickening or condensation of the elastic coat, and constitutes the first step or stage between the dilatable stricture or the curable permanent, and the incurable one; the extent, great obstinacy, or narrowness of obstruction being no proof, although it may be a presumption of the more incurable nature of the disease, inasmuch as some of the most permanent cures I have effected, and which have stood the test of years, have been made where the obstruction was great, and the obstacle nearly impassable by the smallest instrument.

It has been said, that strictures are formed by excrescences, caruncles, or tubercles, growing from the wall of the urethra. I have never seen, after death, any thing of the kind, or any irregularity of this nature, beyond very small projecting points on spots which appeared to be caused by the common inflammatory process. I by no means, however, intend to deny the possibility of such growths, because I have felt, on several occasions, a sort of soft obstruction, which always bled freely until removed, and which might have arisen from excrescences of this nature; and more particularly, because I have seen two cases in each of which an excrescence grew from the side of the urethra, about half an inch from the orifice. In both cases they resembled four or five granulations, adhering to and growing from each other. They were cured with some difficulty by pinching them with forceps, and applying caustic to the part from whence they grew. These cases would lead to the belief, for I know no reason to the contrary, that a similar disease may take place in other parts of the canal where it cannot be seen.

The urethra may be generally, although slightly, thickened for a certain extent, and the surface of the internal membrane changed in its appearance and altered in its function, without any positive obstruction to the passage of urine ever taking place, and without much prospect of a perfect cure being ever effected. A gentleman came under my care, sixteen years ago, with stricture five inches from the orifice of the urethra, through which a solid silver bougie could not be passed, although a similar sized soft one could, and this peculiarity remained until his death, which took place last year. Whenever the canal con-

tracted a little a solid bougie would not pass; whenever it was dilated, so as to admit a No. 10, it would then pass, although not so easily. This gentleman died of apoplexy, having been in the habit of passing a bougie twice a month or oftener, and of showing himself to me every year, or two years, and I had the opportunity of examining the urethra. For the extent of an inch the canal was altered in colour and appearance, being yellower and rougher than the remaining part, and the wall was a little thickened generally, but there was no particular thickening at any one part; so that the disease, in all probability, arose from inflammation attacking the urethra for the extent of an inch, and giving rise to a similar alteration for the same distance. The sensation communicated on passing a bougie was that of its going over a rough hardened surface for some extent, and the dissection proved the fact. The difficulty in introducing a solid sound arose from the length of the inelastic part, and from its being beyond five inches, and more firmly attached at and below the pubes at that part.

In the generality of stricture cases, the state of parts is exactly the reverse, and the obstruction which may have even proved fatal, does not exceed an eighth of an inch in thickness. When it is of greater extent, it is usually believed that two or more distant points of inflammation have each given rise to contraction, and, by frequent recurrences, implicating the intermediate parts, so as to cause an affection of the whole, and, at last, under repeated attacks of irritation, a large, hard, cartilaginous mass of disease is formed, not only of the urethra but of the surrounding parts, in which state it is almost incurable even by the knife.

The canal in front of a stricture does not seem to be affected by it, as far as regards its permeability or elasticity. It remains in its natural state, unless affected by inflammation, although the actual surface or anterior part of the stricture itself is often extremely irritable, bleeding not only as well as being very painful on the slightest touch. The part posterior to the stricture is usually considered to be dilated, and a practice of opening the urethra at that part is founded on the supposition, which practice cannot be correct, because the supposition is not always well founded. When the obstruction has been great and of long standing, the urethra behind the stricture is often found very much dilated, but not always so; and this dilatation may take place in every part of the canal. It more frequently occurs, or at all events, is more often observable, when the obstruction is a single one, and in the pendulous portion of the urethra. In order to give rise to it, the obstruction must have been considerable, and the coats of the bladder must have gained in thickness and in power, in proportion as the contractile property of the urethra has been diminished. The bladder, under constant action and straining, thickens, dimi-

nishes in size, and becomes irritable and impatient of its contents; while the urethra becomes dilated, and immediately behind the stricture more irritable than before it. Little is wanting, in such cases, to give rise to complete retention of urine, ulceration at the irritable spot, the effusion of urine into the surrounding parts, and the death of the patient, unless the science as well as the art of surgery are brought to his relief.

LITHOTRIPSY IN DUBLIN.

THE operation of lithotripsy was performed in the Meath Hospital on Wednesday the 18th of December, by Mr. Crampton, the Surgeon-General, with complete success, so far as the first *séance* is concerned. Without meaning to forestall the details of the operation, which it is probable will be communicated by Mr. Crampton, we think it right to mention one or two particulars which will be read with interest by the profession.

From some peculiarity, connected either with the size of the stone or the condition of the bladder, there existed in this case a considerable difficulty in ascertaining the presence of the stone. The man had been sounded by several surgeons before he was admitted into the Meath Hospital, but no stone had been detected. On the first day that Mr. Crampton sounded him he succeeded in ascertaining the existence of a stone in the bladder, but, on two successive trials, it eluded the sound, although the examination was made by several persons, and among others by Dr. Colles and Mr. Cusack, the Surgeons to Steevens' Hospital. The operation for lithotripsy was therefore necessarily postponed on both these occasions. On the 18th, however, Mr. Crampton on visiting the hospital in the morning, proceeded to make another trial. The patient was laid on the ward table, in the same posture and on the very spot where Mr. C. had first detected the stone; and, after a patient examination of the bladder for some minutes he touched the stone, and the contact was audible to all who stood round the table. In a few seconds, the stone was seized by the instrument, and its dimensions, by the scale on the handle of the instrument, was found to be six-tenths of an inch; by two smart stroke of the hammer it was broken into pieces. One of the fragments, which measured four-tenths of an inch, was then seized and broken by a

single blow. The instrument was then withdrawn, and the patient returned to his bed in high spirits; some small portions of the calculus (which was composed of uric acid) were found between the teeth of the instrument, and a quantity of the detritus has since been passed with the urine.

20th Dec. The operation has not only been unattended by any subsequent increased uneasiness in the bladder, but the patient declares that he suffers less pain than he did previous to its being performed.

[We are happy to see that our hospital surgeons are disposed to practise lithotripsy, and we are glad that so excellent and dexterous an operator as the Surgeon-General should be the first to set the example. We sincerely hope the time is not distant when the dangerous operation of cystotomy will be as rarely performed as trephining is at present.—Eds.]

STATUTES OF THE UNIVERSITY OF EDINBURGH, RELATIVE TO THE DEGREE OF M.D.—1833.

SECT. I.—No one shall be admitted to the examinations for the degree of Doctor of Medicine who has not been engaged in medical study for four years, during at least six months of each, either in the University of Edinburgh, or in some other University where the degree of M.D. is given; unless, in addition to three *anni medici* in an University, he has attended, during at least six winter months, the medical or surgical practice of a general hospital, which accommodates at least eighty patients, and, during the same period, a course of Practical Anatomy; in which case three years of University study will be admitted.

SECT. II.—No one shall be admitted to the examinations for the degree of Doctor who has not given sufficient evidence,—

1. That he has studied, once at least, each of the following departments of medical science, under Professors of Medicine, in this or in some other University, as already defined, viz.: Anatomy; Chemistry; Materia Medica and Pharmacy; Institutes of Medicine; Practice of Medicine; Surgery; Midwifery, and the Diseases peculiar to Women and Children; General Pathology; Practical Anatomy (unless it has been attended in

VOL. IV.

the year of extra-academical study allowed by Sect. I.)—during courses of *six months*.

Clinical Medicine; that is, the treatment of patients in a public hospital, under a Professor of Medicine, by whom lectures on the cases are given—during courses of *six months*, or two courses of *three months*.

Clinical Surgery; Medical Jurisprudence; Botany; Natural History, including Zoology—during courses of at least *three months*.

2. That in each year of his academical studies in medicine, he has attended at least two of the six months' courses of lectures above specified, or one of these and two of the three months' courses.

3. That, besides the course of clinical medicine already prescribed, he has attended, for at least six months of another year, the medical and surgical practice of a general hospital, either at Edinburgh or elsewhere, which accommodates not fewer than eighty patients.

4. That he has attended for at least six months, by apprenticeship or otherwise, the art of compounding and dispensing drugs at the laboratory of an hospital, dispensary, member of a surgical College or Faculty, licentiate of the London or Dublin Society of Apothecaries, or a professional chemist and druggist.

5. That he has attended for at least six months, by apprenticeship or otherwise, the out-practice of an hospital, or the practice of a dispensary, or that of a physician, surgeon, or member of the London or Dublin Society of Apothecaries.

SECT. III.—No one shall obtain the degree of Doctor who has not studied, in the manner already prescribed, for at least one year previous to his graduation, in the University of Edinburgh.

SECT. IV.—Every candidate for the degree in medicine must deliver, before the 24th of March, of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine:—

First, A declaration, in his own handwriting, that he is twenty-one years of age, or will be so before the day of graduation; and that he will not be then under articles of apprenticeship to any surgeon or other master.

3 A

Secondly, A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates.

Thirdly, A medical dissertation composed by himself, in Latin or English; to be perused by a Professor, and subject to his approval.

SECT. V.—Before a candidate be examined in medicine, the medical Faculty shall ascertain, by examination, that he possesses a competent knowledge of the Latin language.

SECT. VI.—If the Faculty be satisfied on this point, they shall proceed to examine him, either *visd voce* or in writing; first, on Anatomy, Chemistry, Botany, Institutes of Medicine, and Natural History bearing chiefly on Zoology; and secondly, on Materia Medica, Pathology, Practice of Medicine, Surgery, Midwifery, and Medical Jurisprudence.

SECT. VII.—Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of the third year of their studies, shall be admitted to it at that time.

SECT. VIII.—If any one, at these private examinations, be found unqualified for the degree, he must study for another year two of the subjects prescribed in Section II., under professors of medicine, in this or in some other University, as above defined, before he can be admitted to another examination.

SECT. IX.—Should he be approved of, he will be allowed, but not required, to print his Thesis; and, if printed, forty copies of it must be delivered, before the 25th day of July, to the Dean of the Medical Faculty.

SECT. X.—If the candidate has satisfied the Medical Faculty, the Dean shall lay the proceedings before the *Senatus Academicus*, by whose authority the candidate shall be summoned, on the 31st of July, to defend his Thesis; and, finally, if the Senate think fit, he shall be admitted, on the first lawful day of August, to the degree of Doctor.

SECT. XI.—The *Senatus Academicus*, on the day appointed, shall assemble at ten o'clock A.M., for the purpose of conferring the degree; and no candidate, unless a sufficient reason be assigned, shall absent himself, on pain of being refused his degree for that year.

SECT. XII.—Candidates for graduation shall be required to produce evidence of their having conformed to those regulations which were in

force at the time they commenced their medical studies in a University*.

JAMES SYME, *Prof. of Clinical Surg.*
Dean of Faculty of Medicine.

WILLIAM HAMILTON, *Secretary to the*
Senatus Academicus.

The general views with which alterations in the course of study for the degree of M.D. in this University have been at different times proposed in the University, and the difficulties attending the subject, have been repeatedly stated in this Journal (*Edin. Med. and Surg. Journal*), particularly in a long paper on Medical Education by the late Dr. Duncan, in vols. xxvii. and xxviii.

It was there distinctly pointed out, that, in a country where no general regulations for medical education are made by the state, and no monopoly of any kind of practice is granted to the possessors of the medical degree, changes of this kind, in order to become real improvements, must be cautiously and gradually introduced; that such an extension of the course of study as might deter many young men from aspiring to the degree, could neither be expected from the University, nor be bene-

* Candidates who commenced their University studies before 1825 will be exempted from the fourth year of attendance (*Sect. I.*), from the additional hospital attendance (*Sect. II. art. 3.*), from the necessity of a year's study in Edinburgh (*Sect. III.*), and from any attendance on Clinical Surgery, Medical Jurisprudence, Natural History, Military Surgery, Practical Anatomy, Pathology, and Surgery distinct from Anatomy.

Those who commenced between 1825 and 1831 will be exempted from attendance on General Pathology, and also on Surgery distinct from Anatomy.

Those who commenced between 1825 and 1833 will be required to attend only two of the following classes, viz.:—Clinical Surgery, Medical Jurisprudence, Natural History, Military Surgery, Practical Anatomy.

And those who commenced before 1833 will be exempted from the attendance specified in *Sect. II. arts. 4 and 5.*

N.B. The attendance on Midwifery in an University (*Sect. II. art. 1.*) is required of all candidates.

ficial to the public,—because its effect would be to swell the numbers of medical men practising in the inferior degrees, and contenting themselves with an inferior education, and to lower, instead of raising, the average attainments of the profession; but that, on the other hand, in so far as additions to those attainments, which are useful and creditable to medical men, could be secured in the graduates without any material diminution of their numbers, a clear and important advantage would be obtained for the public; and that any University which neglects the means in its power for obtaining this advantage, neglects one of its obvious and important duties.

At the time of the alteration of the statutes in 1825, the Professors were convinced, that the course prescribed for the degree,—then comprising only three winters of medical study, hospital attendance, during one of these, and attendance on seven classes,—might be safely and beneficially extended; and in proof of this it was observed, that “*the courses of study then prescribed were much short of the usual practices of the candidates*”;—that, therefore, to the great majority of these gentlemen, the possession of a degree, granted under such rules, did not mark, so strongly as it ought to do, the amount of time and labour which they had bestowed in qualifying themselves for it; and that to a certain number, fortunately comparatively small, who did not voluntarily make up for the deficiency in the prescribed course of study, an undue encouragement was held out, to aspire to the highest honours in medicine, without such a degree of preparation as, at the present day, ought to precede the acquisition of them;—that, in fairness to the students, therefore, as well as from regard to the character of the medical school, and the interests of the public, it seemed manifestly expedient, and was accordingly (the decided wish of the profession, that the course of study required by the University should correspond more nearly to that which *the practice of the best informed students had shown to be necessary* for a complete medical education.”

That the Professors had judged correctly in their anticipation of the effect of the change then made, appears undeniably from this fact. The alterations then made comprehended, excepting in certain cases of rare occurrence, an additional year of study, and in all cases

attendance on three additional classes, and on an hospital for double the time formerly required. Now, after these regulations had come into full operation, the number of candidates for graduation was found, on an average of five years, to be almost exactly the same as in the last five years before they had been proposed.

Dr. Duncan announced, in the paper formerly quoted, that, if the results of the previous changes should prove as satisfactory as was expected, other improvements were contemplated by the Professors.

In the year 1831, another addition was made to the course of study, in consequence of the institution of two new Professorships (those of General Pathology and of Surgery) by the Crown, and of a subsequent act of the Town-Council. Of the propriety of requiring a full and separate course of the latter subject at least, after a distinct professorship of it existed in the University, no doubt could be entertained.

The alterations made by the statutes now published are, in fact, to a less extent than those made, either by the statutes published in 1825, or by the addition of new chairs to the faculty in 1831; but they complete the amount of medical attendance in universities which has been in contemplation; and they have been mainly grounded, like the changes in 1825, simply on the careful observation of the actual practice of the great majority of the successful candidates; and, therefore, in fact, enjoin no more than experience has already proved to be within their reach, and to be practically important to them.

By the first article of the new statutes, two of the exceptions to the four years of university medical study, formerly admitted, but very seldom claimed, are struck off; and the only exception to that rule now admitted is attendance during a winter, distinct from the years of university attendance, on a general hospital, and at the same time on a dissecting-room, not necessarily connected with a University. This provision limits the privilege of aiding the qualification for the degree to those hospitals where there are schools of medicine; but allows one *annus medicus* to be constituted wherever the student has an opportunity of prosecuting those two essential branches of his education together.

By the second article, what has usually

been called the list of optional classes is abolished. Military Surgery (as is fitting in a time of profound peace) disappears from the statutes. Practical Anatomy in a University is made imperative on those who do not avail themselves of the permission to take this branch of their education in the year of extra academical study already allowed; and three months' courses of Clinical Surgery, of Medical Jurisprudence, and of Natural History, including, and of course chiefly consisting of Zoology, are made imperative. Thus, instead of being required to select two courses out of five, the candidate has four courses prescribed for him; and the addition consists of two three months' courses; but in the very common case, where a winter is spent in hospital attendance, with Practical Anatomy, in an extra academical school,—it consists of one, the three months' course only.

Of the three last-mentioned classes, the two first were previously required of that large portion of the Edinburgh graduates who take likewise the diploma of surgeon in Edinburgh. The addition of the Clinical Surgery was strongly urged on the Senatus by many most respectable members of the profession in 1825; and the chief reason then stated against it (the want of clinical surgical wards in the Infirmary) has since been removed by an act of the managers. Medical Jurisprudence has become so important a study, and is required by so many of the inferior boards of medical education, that its exclusion from the course of study, in a University where it is so well taught, would have been discreditable; and Zoology and Comparative Anatomy have now assumed such importance in general science, and are so generally admitted to form the only true foundation of a comprehensive system of physiology, that no course of medical education can be held to be complete or scientific, which does not comprehend at least an outline of those subjects. The full course of Natural History is already attended by a majority of the graduates.

The whole number of courses of study thus prescribed is fourteen; and the books of the faculty show, that the average number of courses which have been actually attended by each candidate for graduation of the two last years has been about twenty. This statement shows that the "members of the University are still aware of the advantages which

medical students derive from various extra-academical studies, and of the propriety of leaving room for them in the arrangement of the course they prescribe;" although, the addition to the number of medical chairs in the University has rendered it less necessary than formerly to make this allowance.

The 4th and 5th articles of the new statutes may be said to be a virtual recognition of apprenticeship, as assisting the qualification for the degree; and to those who have not been apprentices, (and who are at present only a minority of the graduates,) point out the means of attaining the most valuable parts of the information,—particularly as to the practice of pharmacy, and as to certain classes of diseases (such as those of children) rarely seen in hospitals,—which are to be learnt by means of apprenticeship. *These regulations only express in words the actual practice of the great majority of the late candidates for graduation.* Of 110 graduates this year, 102 had voluntarily acted up to the first of these and 8 to the second; and one great advantage of their enactment is, that it will enable the University to claim for all the graduates (it is hoped successfully) the privilege of acting as general practitioners in any part of the United Kingdom, where it may suit their interest to do so.

On the whole, it is particularly to be observed, that the propriety of these new regulations does not rest on merely speculative grounds, but may be said to have been already ascertained by the practice of all the best informed of the graduates for some years past; whose whole course of study and attainments have been under the careful observation of the Professors; and of whom it is but justice to say, that, if they are not eminently worthy of the confidence of the public, it must be very much the fault of their teachers; for their own zeal, diligence, and disposition to avail themselves of all opportunities of instruction, have certainly not been exceeded in any age, or in any school of medicine.

ACADEMIE DES SCIENCES.

December 9th, 1833.

The Weight of Man at Different Ages.

We extract from the last number of the *Journal de la Société des Sciences Physiques*, and which was presented to the Academy, the sub-

stance of an article by M. Quetelet, on the gravity of man at different ages.

There exists an inequality both in the weight and height of infants of both sexes; the average weight of the male being about six pounds and a half, that of the female four pounds and three-quarters, that of the former being 496 centimetres, that of the latter 493*.

The weight of the infant slightly diminishes to about the third day after birth, and does not again commence to increase until after the first week.

At any given age man is more weighty than woman, except near the 12th year, when both average nearly the same.

At the time of puberty, or when the male and female become completely developed, they weigh almost exactly twenty times more than at the moment of birth, and their height is only about three times and a quarter that which it was at this epoch.

In old age the male and female lose from 12 to 14 pounds of their weight, and 7 centimetres of their height.

At about 40 man attains the maximum of his weight, the female at 50. The average weight of an individual, without reference to age or sex, is about 176 pounds, or as regards sex, for man about 188, woman about 170.

Reviews.

Surgical Essays, the result of Clinical Observations, made at Guy's Hospital. By B. COOPER, F.R.S., Senior Surgeon of Guy's Hospital, Lecturer on Anatomy, &c., &c. 8vo. pp. 281. Four coloured plates. London: 1833. Longman and Co.

THE design of the author of this publication is to give a series of cases, systematically arranged, and the views that led to their treatment. He thinks it a great advantage to the profession that the surgeon should be the narrator of his own reports, as "his matter is not distorted by passing through another medium; and being himself only answerable for its authenticity." Such a report, in his opinion, resembles a course of clinical lectures. We cannot, however, agree with him, that a surgeon's reports of his own cases are so very

advantageous, or so much more preferable to those given through another medium, we mean, of course, an impartial one, as he seems to imagine; because it does not always happen that such reports are fairly given, as we well know, from a long connexion with clinical surgery. In stating this, we by no means question the authenticity of the cases related in the work before us; but it some way or other often happens, that many of our hospital surgeons are bitterly opposed to the publication of clinical reports in the medical journals; and, by the way, none more so than the staff of Guy's Hospital. Favourable reports and successful results are very agreeable, but fatal or mismanaged cases may not see the light. We differ so much from Mr. Cooper on this head, that we have repeatedly declined to allow physicians and surgeons to appoint reporters. We have said to them, "your cases shall be fairly and impartially reported; our reporter, if you please, shall submit his notes to you for correction; but he shall be our, and not your reporter." It is only justice to declare, that a preponderating majority of the medical officers of the metropolitan hospitals have readily agreed to our terms; but some declined them, and caused our reporters to be excluded. We therefore argue that the position of our author is valid to a certain extent only.

He goes on to describe the advantages of hospitals to the poor, and to the medical students; to the latter, when there is a medical school, in which the principles of instruction are communicated, and an opportunity offered, at the same time, of seeing them verified in practice.

The contents of this volume are the following:—The Physiology of the Growth and Reparation of Bone—on Fractures in general, including those of most of the bones—Diseases of Joints—on Dislocations, comprising the various kinds—and on Wounds and Injuries of the Abdomen.

These subjects are very ably treated, and the latest information relating to them is communicated. The principles and practice inculcated, are those of our most eminent surgeons, and the success resulting from the treatment employed, proves the author to be exceedingly well acquainted with modern surgery. Each section of his work contains several cases, and as selections from these would be no fair specimen of the whole, and as our limits do not

* A metre is about three feet eleven lines and a half of ancient measure.

allow us to make lengthened extracts, our readers must content themselves with the opinion we have already given of the execution of this work.

Illustrations of the most celebrated Medical and Surgical Works; comprising a complete system of Morbid and Descriptive Anatomy. Part I. Six Plates. Dulau and Co.

THIS is the first part of a weekly publication commenced at Brussels, and intended to comprise the plates of the most celebrated foreign writers, Bourguery, Jacob, Cloquet, Tiedemann, Blandin, Duvergie, Cruveilhier, Munz, Alibert, Velpeau, Breschet, Manec, Boivin, and Duges. There are six plates weekly with separate title-pages, so that those of a similar nature may be bound together, and form a complete work. The plates may be had separately, and the price is more moderate than of any similar production ever offered to the British public. The plates are executed with great fidelity, the descriptions concise, yet comprehensive, and the expense is so trifling, that every student and practitioner ought to possess this splendid and valuable work. We wish the enterprising publishers every success, and we think that in offering this, and most of the foreign works at a much lower price than they can be procured in general, they deserve the encouragement and patronage of the profession. The value of anatomical plates to students and practitioners is inestimable, especially to the majority of the latter, who have neither time nor opportunity of refreshing their memory by actual dissection. The practical surgeon very soon forgets minute anatomy, though the knowledge of it is rigidly exacted for examination at the Colleges, but his fame depends on his recollection of surgical and morbid anatomy, as these will guide him in the responsible duties of his profession. The plates before us illustrate descriptive, surgical, morbid, and obstetrical anatomy, and when we inform our readers that each plate, with a description, is published at three-pence, the cost of a bad cigar, we are inclined to think that our junior, as well as our practical friends, distressed as the profession is, cannot complain of the expense. Indeed looking at the various plates now in course of publication, we are really surprised at their excellence and cheapness; those of Quain and Dermott, for descriptive

and surgical anatomy, are admirable, those of Hope on morbid anatomy, are invaluable, but those of Carswell and Bourguery, have not been sent us, and, therefore, we shall give no opinion of them. As faithful journalists we are bound to state that both are much more expensive, though in our judgment, by no means so well executed, as the work that gave rise to these remarks.

Surgical Observations on the Restoration of the Nose, and on the removal of Polypi and other Tumours from the Nostrils; from the German of Dr. Dieffenbach, of Berlin, with the History and Physiology of Rhinoplastic Operations, Notes, and Additional Cases. By JOHN STEVENSON BUSHNAN, M.R.C.S. Ed., &c. Twenty-two Plates. 8vo. pp. 155. London: 1833. Highley.

THE translator of this work is entitled to great praise, for the accuracy and fidelity with which he has given the researches of the celebrated German professor; and his history of the Rhinoplastic operations, with cures, proves him to be well acquainted with all that has been written on the subject. His appendix contains all that has been done in this country, so that his work may be fairly looked upon as the best in our language. The hospital surgeon, as well as he who practises exclusively in private life, ought to possess it, and the general reader, will find it a curious and interesting work.

Our author has since published "the history of a case in which animals (worms) were found in the blood drawn from the veins of a boy, with remarks."

Though we have fairly given Mr. Bushnan just praise as a translator, and as a zealous cultivator of science, we cannot help advising him to be cautious in future as to the marvellous, and before he indulges in this department, to consider maturely, and reflect on what has been published on any subject, which he chooses to bring before the profession. We are ready to admit, and it is a pleasure to us to do so, that he is an industrious and hard-working young practitioner, and as such, we are ready to encourage him; at the same time we must give him a gentle hint, and hope he may profit by it, for it is well meant; let him avoid the rock upon which many young men split—avoid the marvellous.

MEDICAL REFORM.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—You are fully aware that the plan of establishing one great College of Medicine, affording one degree in medicine to all, or *faculty*, as the medical fashionables term it, has been lately extensively discussed in various medical meetings.

The opponents to this plan have asserted that it will be a means of *levelling* our present institutions. That the establishment of one great school of medicine would build up monopoly upon a firmer basis, and have the effect, by its mere name and influence, of destroying the private schools, so as to do away with that degree of competition so necessary to the furtherance of knowledge. That it would be an attempt to establish an equality of rank in the profession which is improper, not only on account of medical men possessing individually different degrees of talent, and that for different branches of professional education, but also because various professional appointments, trusts, and offices require various grades of professional attainments, and consequently diplomas, as a test of those attainments.

With regard to the levelling of our present institutions, whether they may attempt to stigmatise us with the term levellers or not, I can only say, that the advantage would be on the public side if a better, or better ones, were established instead; and therefore there is no solid reason why these medical rotten boroughs should be saved, because some interested individuals happen to have a great veneration for them.

As to the fact of one great school of medicine having the effect of increasing medical monopoly, that will not depend upon the existence of one great school, because it is a great school, but it will be altogether dependent upon the system upon which things shall be conducted within the walls of that establishment. If a complete system of competition of talent, concours, were established in the election of professors, sub-teachers, and candidates of all sorts, unalloyed by government influence and private intrigue, then such an institution would be the meridian sun of science to Europe; but if the same system reigned in it as is predominant now in other

institutions, it would be one of the greatest fabrics of monopoly ever produced by the foolishness of man; and it would be at some future period, like the church, another great prop to a Castlereagh type of government.

Another thing necessary to prevent monopoly and favouritism in such a college would be to do away with the certificate system altogether, as so often and so ably insisted upon by Mr. Wakley. Let them examine their candidates, and pass them upon the strength of their medical knowledge and for no other account, disregarding from what quarter they procured their information; then no private or public lecturer could be afraid, of being destroyed by the Leviathan, for if it did him no good, it could do him no harm.

The fees in this college ought also to be on a liberal plan; and I must also observe that only one college of medicine would by no means do for England, Ireland, and Scotland; the poorest students are generally the most talented and industrious; and if there were no golden bar of obstruction in their way, they would be the persons who would, as a general rule, rise to the greatest eminence in the profession; it can no longer be denied or concealed that knowledge is no longer confined to the monied persons and the aristocracy. The expense of travelling from Ireland or Scotland to London, as well as of living in the metropolis would be incompatible with the pockets of many; and thus, much talent would be shut out of the profession in those parts distant from London. It would therefore be absolutely necessary, for the purpose of adapting the system to the present age, and to the convenience and common rights of all, that at least three colleges for the "United Kingdom" should be established.

As to the fact of one diploma for all having a tendency to produce too great a degree of equality, and of underrating instances of extraordinary proficiency of talent, I must beg leave to deny it. Diplomas, as they stand now, are positively, with few exceptions, good for nothing,—are no test; and, save and except the useless jargon of Latin, the examination at the College of Physicians is much the same as that at Apothecaries' Hall; but, of the two, the latter, with regard to *materia medica*, chemistry, and practice of physic, has much the superiority. I may also instance the medical examinations at the Colleges of

Oxford and Cambridge being of the same type, while the foundation for a thinking mind to build upon, viz.—a thorough acquaintance with anatomy and physiology are thrown into the back ground; and it is also well known that many men who now figure as M.D.'s, after having been general practitioners, were dubbed Doctors by purchase in Scotland, without undergoing any extra medical education or examination, and even without visiting the last-named country at all. Although a diploma common for all, in connexion with a good public examination, would be a test of the person possessing such a proportion of knowledge as to be safely intrusted with the lives of his fellow beings, it does not follow but that superior attainments in certain branches should be necessary for public professional appointments, and the obtaining of the latter should be conducted by *concours*. With regard to the election of candidates for professional appointments on account of their professional proficiencies and knowledge alone, such a case, I think, I may safely say, never occurs at the present day; but this is effected by the intrigues of interest and money; and a desirable alteration in the state of these things cannot exist without the adoption of *concours*. Those two monsters now oppressing and mortally murdering society,—the influence of money and aristocratic interest, must be laid low before talent and industry, as angels of light, shall preside over the world. It is a mistaken notion to suppose that if a more liberal state of society existed, and if talent and industry were not crippled and bound by the chains of money and aristocratic influence, that all men would or could aspire to be on the same level.—No: all men would find their proper station in society, by exercising what degree of talent they possessed, as different men possess different degrees of that; so some would rise into the higher walks of life, and others would sink into the humbler and more mechanical occupations in society. Society would then be a perfect harmonious whole, and a system of co-operation, or what is nearly the same thing, fair competition established by just laws, would be the cause of a future millennium of knowledge, which must, I think, precede, or go hand in hand with, a religious millennium.

Your obedient servant,

G. D. DERMOTT.

TREPINE IN TOOTHACH.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—As the object of your work is to elicit truth on all medical topics, you cannot, of course, be held responsible for the opinions of your correspondents; it is enough that you give them a fair field for the display of their theories, well assured that the discussion, even of an absurd doctrine, may lead to valuable results.

In No. 98 of your Journal is an article "On the Use of the Trepan in Toothach." In this agreeable communication M. Fattori proposes to relieve the toothach by perforating the tooth with a trepan, and dividing the nerve, or as I would say the pulp, which fills up the dental cavity. But of what avail will this remedy be when the toothach arises, as it most frequently does, from inflammation of the periosteum and not from the pulp? Here, at all events, the operation must be useless. But I go further; I say that in no case can it be advisable, and the proof of the assertion lies in a very narrow compass. If the pulp be in a state of active inflammation, the torture, occasioned by dividing it, would be too much for any one to endure, and might produce epilepsy or tetanus, or even death, according to the greater or less degree of constitutional irritability in the patient; the pain of extraction, in its severest form, would be nothing to it, for the portion of the nerve, rent in that operation, is thinned down almost to a filament, instead of its being, as it is in the body of the tooth, a mass of the highest sensibility. If, on the other hand, suppuration have succeeded, this trepanning would be useless, for either the pus would be taken up by the absorbents, or, as all matter tends invariably towards the surface, it would find a way out for itself in the thinnest part of the socket, where there is the least opposition, and be discharged through the medium of a gum-boil.

This pretended remedy was however tried some years ago, and found worse than useless. The late Mr. Joseph Fox was, I believe, the first that suggested it; at all events he carried it into practice, but finding its utter worthlessness he at once abandoned it, and stated so much, both in his lectures and in his printed

essay, with the spirit and candour of one who knew that his talents and integrity were alike unimpeachable.

I remain, Gentlemen,
Your very obedient servant,
J. N.

CASE OF CYNANCHE LARYNGEA.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I here forward you an account of a case of that uncommon disease, cynanche laryngea, which fell under my observation, and which was successfully treated by mercury and venesection.

I have the honour to be,
Gentlemen,
Your obedient humble servant,
G. G. HOLMES.

Mary Belton, aged 22, was taken ill with pain on inspiration, which afterwards increased to so great a degree, that respiration was carried on only by the most violent efforts attended with great pain, total loss of voice, and impossibility of deglutition. Pulse 120, with pain increased by pressure on the thyroid cartilage.

Dec. 12. Venæsection ad 3 xx.
Hirudines xvj. gutturi.
Hyd. submur. gr. xxiv.
Pulv. antim. gr. xij.

Fiat pulv. vj. capt. j. 3tiâ horâ.

Vespere. Was much relieved by the bleeding; breathing easier; can articulate faintly; pulse 80; bowels confined.

Haust. cathart.
Hyd. submur. gr. xij.
Pulv. antim. gr. vj.

Fiat pulv. vj. Capiat ut antea.

13. Has had several fainting fits on the previous night; pulse 70; salivation produced; bowels have been well opened; breathing much better; can speak with more distinctness; pain not so great on pressure.

Potass. nit. ʒ ij.
Vin. ipecac. 3 ij.
Mist. camph. ʒ vij.

Capiat coch. ij. amp. 3tiâ horâ.

14. Difficulty of breathing decreased; bowels confined; voice somewhat better; pulse 90.

Hirudines xij. gutturi.
Pergat haustu et misturâ.

15. Breathing and voice still better; bowels open; pulse 70.

Emp. lyttæ gutturi. Pergat misturâ.

17. Was considerably better, but complains of pain in swallowing; pulse 80; bowels regular.

Pergat mistura, et adde tinct. benz. co. 3ij.
c. mucil. acaciæ.

19. Is almost recovered; pain on swallowing and breathing entirely gone; can take her meals pretty well; bowels confined.

Pergat. mist. et haust. cath.

20. Is now going on as well as could be wished.

THE

London Medical & Surgical Journal

Saturday, January 4, 1834.

ST. ANDREW'S, OXFORD, EDINBURGH,
THE DEVIL, AND MEDICAL RE-
FORM.

THAT the medical corporations would make no effort to avert the certain dissolution which awaited them in their inert state, was not to be expected. It matters not how much their present activity stultifies their past conduct: the smallest chance of success engenders hope; and certainly these learned bodies calculate but too justly on the infirmities of human nature, in daring to expect, that by sudden and violent exertions of their controlling power, hitherto abused by being suffered to lie dormant, and now put forth under the pressure of fear, they may disarm the friends of rational reform, and induce the superficial to believe, that there is no necessity for the interference of Parliament in medical politics.

We cannot begin the new year better than in warning the profession against these deceptive arts. We expect many imitations of the example of St. Andrew's. Oxford has taken the hint, and has boldly avowed, what hitherto it was treason to utter, that her medical department was

utterly unsuited to the times. How far this confession may affect the character of the gentry, who presume to lord it over their brethren on the strength of university qualifications, we beg to suggest as an excellent subject for Sir Henry Hallford's next essay at the College of Physicians. Our present number contains a new illustration of ultra-conservative tactics:—the University of Edinburgh having thrown up a straw, in the Scotch bill of last session, to see which way the wind blew, has declared itself for Reform, and has promulgated a new course of medical education, which our readers will find in this number. The Spanish proverb says, "Hell is paved with good intentions;" and it seems our Scottish neighbours have been Macadamising the infernal regions for these five years past. His Satanic Majesty may thank them, if he please, for their services; the profession owes them no thanks. Instead of aiming at promoting the dignity and advancement of the profession of medicine, we suspect that our friends, with their characteristic worldly wisdom, are merely striving to share the good things of England with the Apothecaries' Hall;—dealing in drugs is an excellent way for turning a penny.

When the whole dozen of Universities, Colleges, Faculties, and Warehouses shall have each announced its improved curriculum of education, what an agreeable diversity will be found in the arts of acquiring medical science; what grades of knowledge a discerning public will detect! One college will recommend itself by exacting six months' attention to pharmacy; too short cries a second, it is a twelvemonths' study at least; nay, you are below the mark, says a third, two years' is the minimum of pharmaceutical study; and then government, having naturally no confidence in the several plans

of medical education, will lay down its own standard of knowledge for those who are to be intrusted with the health of a common sailor or soldier.

But it is unnecessary to follow out these discrepancies. Supposing that there is nothing objectionable in the rank of the profession, or in the legal rights of its members, or in the ordinary mode of practice and remuneration; granting that there is nothing in the governing bodies to be altered from without; let education alone be the question, and we put it confidently to any reasonable mind, whether the separate action and private interests of the medical corporations will not absolutely produce, by any mis-called reform emanating from themselves, that very diversity of elementary education, which, above all things, is absurd in medicine. In the last number of the *Medico-Chirurgical Review*, Dr. Johnson has entered into some explanations of the object of his much discussed motion in favour of ONE FACULTY; from which, it appears, that uniformity of education was, in truth, the principle to which the Dr. wished to pledge the Society. The legality of the proceedings, by which the motion was lost, is to be questioned on next Saturday. As Dr. Gregory, who penned the resolution, (so says Dr. J.) artfully insinuates, that by the establishment of One Faculty was meant the abolition of even the names of the existing medical corporations, we think it right to state, that the Doctor's motion was not intended to imply the annihilation of the present colleges or seminaries of education. The Doctor has declared, that if the motion be at all doubtful, he will introduce the principle to the Society in words too clear for doubt, "*that in the opinion of this Society, a more extended and uniform system of medical education than at present exists is highly desirable; and*

that the power of organising and regulating that system of education would be better vested in one body, or faculty, under the sanction of the legislature, than left to the option or caprice of various universities, colleges, corporations, and faculties, each of which enjoins its own peculiar course of study, whereby much confusion and discordance are produced, in a profession where the mode of elementary education ought to be the same for all its members." We consider this principle an excellent rallying point for the independent members of the profession against the intrigues of the corporators. Establish once uniformity of education, and where is the pretence for distinction of ranks? "Since," as Dr. Carrick well observed, "apothecaries and surgeons now act as physicians, the public has a right to expect they should have the physicians education;" and if they have the education, why not the title?

There is a subject, which we know is considered very delicate by general practitioners; the union of the *profession* and the *trade*, can be scarcely alluded to without alarming a host of prejudices. The Medical Gazette, in its labours to support and multiply factitious ranks, cares not how degraded the *second* class of the profession may be. The Lancet is silent. But we are happy to have the co-operation of Dr. Johnson in calling the attention of the profession to this all-important question. We have, on various occasions, stated our opinions upon it; and we have hopes, that our publication of the Report upon Medical Reform in France, will be of use in opening the eyes of the general practitioners to their real interests in this matter. Many of the most respectable members of the class of general practitioners have publicly, and still more have privately, expressed, their annoyance at a system, which degrades

them as members of a liberal profession, to practise the petty arts of a little tradesman.

To accomplish these useful purposes, to raise the standard of education, and make that standard general, to co-operate in purifying medicine from the contamination of trade by wholesome regulations as to fees and professional ethics, are objects well worthy the attention of every independent member of the republic of medicine; and we earnestly call upon every practitioner, who is desirous to discharge that debt, which Lord Bacon says a man owes to his profession, to labour both in private and in those societies where the profession is congregated, for the dissemination and maintenance of these sentiments, as it is only by co-operation that the enemies of medical reform can be resisted.

MEATH HOSPITAL, AND COUNTY OF DUBLIN INFIRMARY.

THIS morning (Dec. 31st) Mr. Crampton repeated the operation of lithotripsy on the patient on whom he operated on the 18th (see page 720 of the present Number). The man was laid, as before, on the ward table. About eight ounces of water were injected into the bladder, and the stone (or rather a fragment of the stone which had been broken in the former operation) was seized at the first effort. It measured, by the scale, a quarter of an inch. Two smart blows of the hammer reduced it to fragments, one of which was seized as quickly and reduced in the same manner. Mr. Crampton then moved the instrument about the bladder, seizing several small fragments of stone between its jaws, and crushing them by the pressure of his hand on the moveable branch of the instrument. The noise produced by the crushing was audible to those who were close to the table. The operation was concluded in about four minutes, and was attended with no pain except what was caused by the introduction and withdrawal of the instrument. Some water was thrown into the bladder, and about twenty grains of the detritus were collected in the vessel, and in the jaws of the instrument. When Mr. Crampton

was about to inject the bladder, the man exclaimed, with true Hibernian humour,—"Ah! never mind doing that, your Honour; sure if I wanted to catch fish, I'd drain the pool sooner than I'd flood it!"

French Medicine.

Peculiar Influence of different Vessels upon Milk.

DR. BOUCHARDAT has found, from experiments, that one of the best ways of preserving milk is not to change it from one vessel to another. Thus, if milk be placed in a tin vessel, and then transferred into one either of glass or pewter, it will not keep good so long as it would if retained in one vessel; a change is produced in it favourable to coagulation. Brimstone preserves milk a considerable time, but it becomes sensibly acid, and coagulates on boiling; vessels also of zinc, antimony, bismuth, brass, copper, and iron preserve it well, but the harmlessness of the first is very doubtful, and one or two of the other metals communicate to it a very peculiar odour. For domestic purposes, therefore, we should keep it in tin receptacles, and avoid changing them. Cheese acquires an odour and taste differing according to the different vessels in which it is prepared, the kind of mouldiness which shows itself is also very different. After keeping fifteen days, ammoniacal products predominate in all the metals, and M. Bouchardat attributes the greater or less rapidity of chemical change in the milk to the electric force which shows itself from the contact of heterogeneous bodies.

Fracture of the Humerus in a New Born Infant.

M. DUBROCA, Surgeon of Barsac, found the left humerus fractured in an infant, born about two hours before; this fracture was evidently caused by the manœuvres of the midwife, who had been too eager to disengage the shoulders, soon after the escape of the head; by means of her finger she had given to the left arm a sort of see-saw motion, and had thus caused a fracture. A suitable apparatus was applied, and on the eighth day the fracture appeared united. M. Dubroca judged it prudent, however, not to remove the bandage until the 15th; at this period there was so much callus, that the humerus was three times its natural size at the

place of the fracture. The tumefaction has since, however, completely disappeared.

Créosote and its qualities.

M. REICHENBACH has lately discovered in pyrolignic acid, and in pitch and tar, a peculiar oleaginous liquid, to which he gives the name of créosote; it is colourless, transparent, and possesses a very peculiar odour, somewhat resembling castoreum; its taste, also, is very caustic, and it is of the consistence of oil of almonds, having a specific gravity of 1.037. Amongst other curious properties, créosote possesses the following:—one drop of it poured upon an aqueous solution of the white of eggs causes coagulation; if we place a piece of flesh in a solution of this liquid for half an hour it may afterwards be exposed to the heat of the sun without fear of putrefaction, and in eight days it becomes quite hard, has a reddish brown colour, and acquires the odour of smoked flesh. Fish may be preserved in the same way, and there cannot be a doubt but that the créosote possesses the same anti-putrescent qualities as the pyrolignic acid and tar water. The action of this oily fluid, on the animal economy is deleterious; if placed on the tongue it causes a violent pain, and if applied to the skin it destroys the epidermis. Insects and fishes, placed in a solution of it, quickly perish, plants also will die if watered with it.

The results of some experiments, as to its remedial properties, are also given by M. Reichenbach, but further observation seems necessary to confirm its value as a therapeutical agent. In one case of burn, a rag wet with a solution of it was applied three or four times a-day with beneficial results, and the discoverer has found advantage from it in two cases of confirmed consumption. Cutaneous eruptions and carious ulcers, and bad suppurations also seem to have been improved by its external application; finally, one drop applied to a carious tooth is considered to be a certain cure.—*Journal de Pharmacie.*

French Hospital Reports.

LA PITIE.

Partial Dilatation of the Heart.

A robust negro, æt. 53, was admitted for palpitation of the heart and dyspnoea; he had difficulty in moving, and was unable to con-

time his employment; the beating was strong and tumultuous; pulse hard and firm; no cedema of the lower extremities. He had for some years been subject to similar attacks, which were relieved by bleeding and quiet, but returned on any exertion; and about twelve months before his admission he had enlarged testicles from gonorrhoea and buboes, for which he was salivated.

Blood was several times extracted from his arm, digitalis and diluents were prescribed, and he was ordered to keep perfectly quiet. By means of this treatment he slowly improved, till the end of February, when the palpitation and oppression in breathing returned; bleeding again somewhat relieved him; but on the third of March the symptoms were renewed, accompanied with dry cough, sharp pain behind the sternum, fever, and erepitating râle on each side of the chest. Leeches were applied to the side, and the pain had completely left him by the 8th; in the evening of the 10th, however, he was seized with a fit of suffocation and suddenly expired.

Autopsy.—Upon inspection the two ventricles of the heart were found much dilated, and the right one loaded with fat; from the apex of the left proceeded an aneurismal tumour, nearly equal in size to both ventricles; it was circumscribed at its origin by a circular band, and adhered to the pericardium and diaphragm for three-fourths of its extent, the remaining part being free; the walls were about a line in thickness, and were formed by a fleshy membrane, a continuation of the exterior muscular fibres of the left ventricle, and by the pericardium; the fleshy fibres were wanting in two places on the right side of the tumour, where two cavities, equal in size to the points of the finger, were found, separated from each other by the prolongation of one of the columns of the ventricle; the anterior of these was only covered in by the pericardium, the posterior by the pericardium and tendinous part of the diaphragm. The lining membrane of the heart appeared to terminate suddenly at a prominent border which separated the left ventricle from the aneurismal tumour. The stomach was slightly diseased, and in the caput coli near to the ileo-colic valve was found a small patch of ulceration; the remaining portion of the intestines was healthy.

Portuguese Hospital Reports.

(Concluded from page 702.)

Two slight Wounds of the Head producing Death, and rendering active a dormant Disease of the Liver.

M. K., a private in the service of the Queen Donna Maria, æt. 35, and of pretty good general health, was struck on the head in two places by an officer with the scabbard of his sword, who was punishing him for mutiny. This produced two wounds of the scalp, one on the left parietal bone and near its anterior superior angle, the other on the middle of the temporal arch. In the former wound a small artery was divided, which to suppress its bleeding required being tied. For the first nine days no symptom of an alarming kind showed itself; the wounds continued sluggish, with no tendency to heal; the patient complained only of little pain in his head, but was always very drowsy and absent in his mind. 6th of January, ten days after he was struck, he had considerable fever of the low kind, great pain in his head, much drowsiness and inattention. To be purged with calomel and jalap, head to be shaved, and cold water to be constantly applied to it.

7th. Has had no sleep; is more feverish, drowsy, and absent; pain in his head more severe; bowels have been well purged. To have a saline draught ter in die; cold applications to be continued.

8th. Is worse to day in every respect; skin is a little tinged with yellow; some pain on pressure in the region of the liver, none in the shoulder. To continue the cold application and draughts, and to take every two hours pil. hydrarg. gr. ij.

9th. Is quite insensible; pupils rather contracted; skin quite yellow. Continue the medicine.

10th. He expired this morning nine a.m.

Autopsy twelve hours after death.—In both wounds the bone was denuded to a very slight extent. The membranes of the brain were inflamed nearly throughout their whole extent. Between the dura mater and the bone, and opposite both wounds of the scalp, was a small quantity of pus, and also along the course of the left arter. mening. med., where the dura mater was ulcerated. Opposite the wound on the middle of the temporal arch

there was matter contained between the dura and pia mater, and here the membrane was most highly diseased. The substance of the brain was healthy.

The liver was found greatly enlarged and inflamed. In its substance was a great number of tubercles, some of which were in a state of suppuration, others inflamed only, and a few appearances were in a dormant state. The other viscera were in their natural condition.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Fracture of the Neck of the Thigh-Bone.

A MAN of very large frame, and about eighty years of age, was conveyed to this hospital, having fallen down on his hip in the street, by which, as it appeared on examination, the neck of the femur was fractured.

At the moment of the fall the patient felt a very severe pain, which was succeeded by complete inability to walk. There was considerable shortening of the limb, and he suffered very great agony at any attempts at abduction. A crepitus was distinctly discovered. There was eversion of the toes, and all the characteristic symptoms of fracture of the neck of the femur were present.

Complete rest and quietude are the only circumstances at all likely to produce any good effects in this case. It has long been a matter of doubt and dispute, whether, in fractures of the neck of the femur, re-union by bone ever does ensue; and Sir Astley Cooper distinctly states, in his opinion on the subject, that ossific re-union never does take place after such an injury. In France, however, a contrary opinion prevails, and some cases which have occurred in that country prove, beyond all doubt, that such re-union does occasionally, but very rarely, follow. In fracture of the neck of the femur, occurring in young persons, the chances are in favour of union; but there is very little or no prospect of such a favourable result when the accident happens in individuals advanced in years. The most trifling violence will cause fracture of the neck of the femur in old persons, in consequence of the brittleness of the bone.

WESTMINSTER HOSPITAL.

Calculus of the Bladder—Lithotripsy by Baron Heurteloup.—Second Operation.

In the case of calculus which we reported in No 97 of this Journal, the patient has gone on most favourably since the first operation. He has voided a considerable quantity of pulverised stone in his urine. There was, however, a good deal of irritability of the bladder, and slight derangement of the system, which

obliged Baron Heurteloup to defer his second operation a week beyond the day he had originally intended to repeat the lithotripsy. The patient did not complain of any uneasy sensation for the last ten days, and seemed to have great confidence in the Baron's operation.

On Saturday, Dec. 7th, Baron Heurteloup proceeded to perform his second operation. The patient was placed in the usual manner on the couch (invented by the Baron), and the operation proceeded with in the same manner as before described.

On the removal of the patient, who, during the operation, appeared to suffer very little uneasiness, the Baron addressed the gentlemen present. In the course of his remarks, he brought forward a man who had been his patient, and on whom he had performed lithotripsy with apparently the most felicitous results. The patient appeared much emaciated, but completely free from any of the symptoms under which he had formerly suffered so much agony.

Baron Heurteloup displayed the pulverised calculus which he had taken from this patient. The quantity was very considerable, and afforded much satisfaction to all present. The Baron then made a few observations of very little general interest, at the conclusion of which he was very warmly applauded.

Third Operation.

Baron Heurteloup performed lithotripsy for the third time on his patient last Saturday (the 14th). The present case appears to be one of a very difficult description. There is a nucleus of stone in the bladder, which is of iron hardness, and, on the last operation, resisted all attempts at pulverisation. The Baron intends to adopt other measures, as the ordinary mode of operating will not, it is apprehended, be effectual in reducing the stone to powder.

The general health of the patient continues excellent, and he walks about the ward, and converses with confidence and certainty of his ultimate recovery. He passes his urine in a good stream, and suffers comparatively little or no pain. Indeed, there is every prospect of the case turning out very favourably. This case is more than unusually interesting, as being a difficult one. We shall not fail to give the result of it in a future number.

MIDDLESEX HOSPITAL.

Case of Fractured Spine—Middlesex Hospital Medical Society.

THE following case is one of great interest and importance, and stands alone, as far as I have been enabled to learn, in the annals of surgery. If similar cases have occurred, the mode of giving this publicity will, no doubt, bring them to light; and thus many valuable facts connected with the physiology of the nervous system in particular, may be given to the profession.

John Neagle, æt. 36, a labouring man, was working in a sewer, and the earth fell in upon him. Several cart-loads were removed before he could be extricated. When he was conveyed to the Middlesex Hospital, it was found that the spine was fractured about the eleventh or twelfth dorsal vertebra, the several ribs were fractured, the left humerus dislocated, and the left tibia and fibula broken in several places, implicating the ankle joint.

Complete paraplegia from the anterior superior spinous processes. There is no sensation in the lower extremities from these points, and the broken leg gave not the slightest pain. The man was placed upon the usual bed for such fractures, the leg was attended to in the ordinary manner, and the humerus reduced. It appeared to be much easier to dislocate this bone again than to reduce it, for the joint felt as if so much disturbed. The house-surgeon states, that even by a single circular motion, the head of the bone, when in the axilla, could be brought into the glenoid cavity, and it required no force to slip it under the pectoral muscle. This fact is noticed in order to show that there was considerable laceration about the joint.

The patient lived in this miserable condition for eighteen days, during which time the following symptoms were noted. During the first few days there was constipation of the bowels; afterwards, and until his death, the *feces* came away unconsciously. The catheter was of necessity employed twice a day, for the first ten days, when the urine dribbled away from him, and became highly ammoniacal. Acute pleuritis supervened in consequence of the injury which the chest sustained. There was never any pain in the fractured leg, the temperature of which was equal to that of the other. The man complained but little, but the countenance always betokened anguish, and his nights were passed without much rest. At length the constitution being worn out by the accumulation of disease, he gradually became more exhausted, and died eighteen days from the time of admission.

Post mortem inspection.—The spine was found fractured transversely at the twelfth dorsal vertebra; the fractured portions were displaced; the spinal cord was pressed upon, and bruised. It was also considerably softened, and some clear fluid found in the cavity about this spot. The arterial system of the whole medulla spinalis was much injected. The shoulder joint had become natural, the breaches made by the dislocation being quite repaired. The ribs also, fourteen of which were broken, were involved in processes of union. Small points of osseous matter were deposited around the fractures imbedded in the periosteum. Upon examining the leg it was found that no union had commenced. The periosteum was not thickened, neither were the integuments, and even the effused blood was not absorbed. It was the unanimous opinion of those who inspected the parts accurately, that they pre-

sented all the appearances of a recent fracture, viz. one which might have occurred only about two or three days. The fracture was very extensive, the tibia and fibula being broken in seven or eight places, and, as was before stated, implicating the joint. Upon raising the leg vertically, the medullary matter oozed from the gaping fracture in a fluid state, and the lamellated structure of the bone at this part was partially deficient, it was softened, and readily broke down. The lungs were found much compressed by fluid, and the pleura was considerably thickened, giving evidence that the most active pleurisy had been going on. The bladder was contracted, and its lining membrane highly vascular and inflamed. The kidneys were large and flabby, exhaling a strong ammoniacal odour when incised.

The foregoing case excited considerable interest among the gentlemen connected with the hospital, as might be expected, and it was brought forward for discussion at the Medical Society of the institution by one of its intelligent members. The debate occupied two evenings, and was conducted in a spirited and talented manner. The majority of the members were of opinion that the want of union in the leg depended upon the absence of nervous influence. This conclusion was arrived at in consequence of reparation going on so perfectly in the upper half of the body, which was in a natural state, while the injury in the lower half, which was in an unnatural state, exhibited no signs of the healing process. The bladder certainly was inflamed, and that viscus was in the lower half of the body, but the bladder had an exciting, irritating, fluid within, which will readily account for inflammation. The question naturally suggested itself, viz. whether any change would have gone on in the leg if blisters had been applied. They might have effected some good result, but this is merely a point of discussion. It was evident that the want of union could not be referred to constitutional debility, because the system was enabled to repair other injuries, and to set up an active inflammation in the chest.

Mr. Mayo was not disposed to agree with the opinions of the Society. He conceived that neither secretion nor the reparation of bones was influenced by the nervous system, and imagined that fracture of the spine would not impede the union of fractured tibia and fibula; consequently he attributed the want of union, if want of union there was, of which he was sceptical, to other causes, viz. to the irritation excited by the coagulum around the bone.

In reply to these observations, it was stated that the effect of paralysis of the fifth pair of nerves was to render the conjunctiva and nostril dry, by suspending the natural secretions, and several cases of hemiplegia in the hospital were brought forward to show that if injuries or burns occur accidentally in the paralysed limbs, it takes months to repair them. One man with hemiplegia spilled some broth upon his arm,

it vesicated, and left an unhealthy tedious sore, which was cured with the greatest difficulty; and a girl, with the same disease, had the paralysed foot burnt with the "foot warmer." This also caused a sore which was slow and tedious in its reparation.

MISCELLANIES.

NEW MOXAS.—M. Ferrari steeps some cotton in a saturated solution of chlorate of potass, and then divides it into cones of various sizes. This is very active. Dr. Jacobsen of Copenhagen dips bands of paper in a solution of chromate of potass. These burn slowly, and are approved of by many eminent French surgeons.—*Journal de Pharmacie.*

M. Begin, one of the Editors of the *Journal Hebdomadaire*, is appointed Professor in the Strasbourg University. The students will be greatly benefited by this appointment.

MEDICAL REFORM.—The Academy of Medicine has unanimously resolved to separate pharmacy from medicine, and agreed that every one, who undertakes the cure of diseases, must be a Doctor of Medicine and Surgery. The fees of physicians and surgeons to vary from one shilling upwards. The apothecaries to be confined to the preparations of medicines and compounding prescriptions.

BOOKS.

The Medico-Chirurgical Review, and Journal of Practical Medicine. Edited by JAMES JOHNSON, M.D., Physician Extraordinary to the King. Jan. 1834.

Vol. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,**Session 1832—1833.*

LECTURE LXXI., DELIVERED MARCH 20, 1833.

GENTLEMEN,—In the last lecture, I was considering the various preparations of mercury employed in the treatment of venereal complaints, and endeavouring to explain to you some of the principles which should regulate the administration of them. I will now make a few remarks on other medicines which are often given in some stage or another of these disorders.

In estimating the anti-syphilitic power of any medicine, or plan of treatment, you should never forget the important truths established by the investigations of Mr. Rose, and other surgeons of the British army; and, in particular, you should remember, that mercury is not absolutely necessary for the cure of the generality of venereal complaints; for, as far as Mr. Rose's inquiry went, it appears that he never met with a case which he could not cure without mercury. Mercury is frequently useful in accelerating the cure, and still more importantly serviceable in lessening the frequency of secondary symptoms. Yet, let not these advantages render us blind to the fact, that mercury is not absolutely necessary for the cure of syphilis; and, in estimating the anti-syphilitic power of any medicine, this truth must never be lost sight of. Sometimes, indeed, mercury, so far from being indispensable to the cure, may have the effect, in particular states of the health, of retarding, or even preventing altogether, the patient's recovery. Frequently the general health becomes bad before a venereal complaint is cured, and then, on the mercury being discontinued, the health improves, and a cure of the syphilitic affection follows. This frequently occurs, and gives a kind of false credit to any medicine which may

have been prescribed after the discontinuance of mercury. It is chiefly, I believe, in this manner that sarsaparilla has acquired the reputation of having anti-venereal qualities:—the patient is taking mercury, and his health suffers; the mercury is left off, and then a favourable change takes place in the constitution, and chancres, buboes, sores, &c., yield, whether sarsaparilla be given or not. Yet, I by no means wish to insinuate that sarsaparilla is completely useless; probably it has a good effect in accelerating the cure, independently of the benefit derived from our stopping or moderating the mercurial course. Nothing can be more various than the opinions about the real efficacy of sarsaparilla:—Dr. Cullen believed that it has no power at all; and it is found, that if you give it to a person in health, it makes no sensible impression on the constitution; it does not affect the pulse; neither does it materially increase any of the secretions. Hence, it is presumed, that when given to a person in health, it possesses little or no power. Fordyce thought it useful in certain complaints that would not yield to mercury; and the late Mr. Pearson, surgeon to the Lock Hospital, who had immense opportunities of trying the effects of various medicines in syphilitic cases, came to the conclusion, that though sarsaparilla was, in a certain degree, useful in venereal complaints, it could not cure them without mercury. The latter part of this opinion we now know is erroneous. He also says, that sarsaparilla is particularly valuable as a means of obviating the pernicious effects produced on the system by a mercurial course; and, in his day, mercury was given copiously; and its action maintained for a considerable time. At the present day, sarsaparilla is commonly given at the end of a mercurial course; and, as far as I have seen, the practice is attended with beneficial effects, restoring the patient to health much sooner than if he did not take the medicine. It is also used as an alterative in various complaints reputed to be venereal, though not exactly possessing the characters of the disease described by Hunter, or those of the scaly venereal disease, as described by Mr. Carmichael. Many affections, arranged with venereal ones, undoubtedly yield

to sarsaparilla, and alterative plans of treatment, even better than to a full mercurial course. You will often find this benefit accrue from sarsaparilla, given either with small doses of the oxy muriate of mercury, or with nitric acid, or antimonial medicines; and numerous cases present themselves which are more served in the beginning, by this method of treatment, than by mercury; though, in a later stage, mercury may be administered with surprising effect. With respect to the compound decoction of sarsaparilla, and the mineral acids, I may observe, that they are all useful in particular stages of the disease, where the health is not in a favourable state for the action of mercury; but whether any of them really possess what is sometimes understood by an antisyphilitic power is a question that resolves itself very much into the consideration, how far syphilis is capable of getting well without mercury, and how far it admits of a spontaneous cure. Certainly it is quite conceivable, that, although the cure of the disease may sometimes be promoted by the discontinuance of mercury, it may still admit of being expedited in a greater degree, when, with this change in the treatment, we join the administration of sarsaparilla, or other alterative medicines. There is another circumstance to which I must direct your attention: you should never forget, that venereal complaints are frequently complicated with common as well as with specific inflammation, and, consequently, that they often call for antiphlogistic treatment. The whole of the inflammation attending the effects of the venereal disease is not specific: a good deal of it is merely common inflammation, and may be benefited by the same means which are usually resorted to for checking inflammation in general:—bleeding, leeches, cold applications, poultices, low diet, quietude, &c.

From these general observations on the venereal disease and its treatment, I now proceed to consider more particularly each of the primary and secondary symptoms.

The term *chancre*, as conveying the idea of an ulcer that has a corroded appearance, is not exactly what ought to be employed; perhaps the expression *primary sore* is preferable. It is not every sore arising from sexual intercourse that is to be considered a chancre; there are many which are supposed to be produced by the irritating action of the secretions of the genital organs more or less changed. Sores, produced in this way, are not uncommonly classed with venereal ones, though not having the aspect which the meaning of the word *chancre* would convey; and for this and other reasons, the use of the term *primary sore* is, I think, more accurate. Primary sores are most frequently situated on the external parts of the organs of generation, and especially on those parts of them which are covered by a thin delicate membrane, as on the inside of the prepuce, and on the glans penis, or corona glandis, in the male subject, and on the labia,

nymphæ, &c., in the female. Primary sores are also sometimes met with in other situations about the genital organs, as on the outside of the penis, on the common integuments of this organ, or on the external skin of the labia pudendorum, and sometimes, as all surgeons now admit, actually within the orifice of the urethra or vagina, though less frequently in these situations than in the others which have been specified. At this present time I am attending a gentleman, whose urethra became so contracted at the orifice, that he was induced to have it divided; but before the cut was well, he got under the influence of wine, and had connexion with a woman, who gave him a chancre completely within the urethra. The formation of chancres on the outside of the labia, in the perinæum, and on the common skin of the penis, seems to prove that the venereal matter may produce ulceration even in situations where a thick cuticle intervenes between it and the cutis, as far as those parts are concerned; for I ought to mention, with respect to the surface of the body in general, that we have no proof that the venereal poison will make any impression unless some excoriation, pimple, wound, or abrasion, happens to exist previously to the application of the matter. You will not find chancres form on the fingers, unless the person happens, at the time when venereal matter is applied, to have an abrasion or wound upon them; in such case, the chancre is produced by a true inoculation, just as has been the case with the gentleman who caught a chancre by having intercourse with an infected woman, while a cut at the orifice of the urethra was unhealed. I am not aware that there is any clear proof on record of a venereal primary sore having been produced on any common part of the general surface of the body, away from the genital organs, unless there had been a wound, ulcer, pimple, or some kind of breach existing in that situation at the period when the matter was applied. Yet, as I have stated, it is a fact, that we see chancres on the common skin of the penis, on the outside of the labia, and sometimes lower down towards the anus. The cases of chancre on the hand or fingers, in consequence of a previous abrasion, ought to induce the members of our profession to pay attention to the state of their hands in practice, and especially to be upon their guard when they have any slight scratch or pimple on these parts, in dressing chancres and venereal abscesses, and also in the practice of midwifery.

I was very recently consulted by a surgeon residing a few miles from town, for what appeared at first to be a most malignant ulceration of one of his fingers, which had annoyed him for several weeks; the part was not only very painful, and the seat of large fungous granulations, but it seemed to be twice its natural thickness, so as to look like a great knob, or ulcerated tumour on the last phalanx, involving it on every side. Now, after various

remedies had been tried for some time, and even the question of amputation had been more than once considered, pains in the limbs came on, followed by a scaly copper coloured eruption. This led to an inquiry into the condition of a woman to whom the gentleman had been officiating as accoucheur, just before his finger began to be bad, and it was then ascertained that she had chancres, sore throat, and eruptions herself. These circumstances made my medical friend recollect another circumstance, namely, that in putting his hand into his waistcoat pocket, a day or two before he delivered this female, he had accidentally pricked his finger with a toothpick, which happened to be there. We now had no longer any idea of amputation; mercury was given, and the cure speedily accomplished.

The period of the commencement of venereal ulceration, after the application of the virus, is very irregular; there is no constancy or uniformity in this respect; [the time is different in different instances. Mr. Hunter has known chancres begin within twenty-four hours after exposure to contamination; then he has met with other cases, in which the sores did not make their appearance till six or eight weeks after coition. I should say, that you will seldom meet with a true primary venereal ulcer sooner than a week after the application of the poison.

Primary venereal sores, as I mentioned to you on a former evening, are of several kinds. The most remarkable one, is that which was so well described by Mr. Hunter, and is called accordingly the *Hunterian chancre*. It is characterised by a tendency to assume a circular form, by its excavated surface, by the tenacious and adherent quality of the matter produced on it, and lastly, and above all, by its hard cartilaginous base and margin. This indurated base and margin terminate in an abrupt manner; the sore seems as if it were placed on a very hard solid mass. This kind of primary sore generally begins as a pimple, or minute vesicle, which enlarges, and soon breaks and ulcerates; generally speaking, venereal ulceration does not extend itself with great rapidity; neither is it the common character of the Hunterian chancre to make quick progress. Nevertheless, exceptions to this statement do occur, and these seem to depend on the state of the health; for when this is in an unfavourable condition, or certain forms of constitutional disturbance and irritability prevail, the ulceration will spread with greater quickness than usual. When the sore is situated on the prepuce, or the frænum, there is usually more inflammation present than when it is situated on the glans, which is a less irritable part. When the ulcer is on the glans, which is also less sensible, it is less painful than when it is on the prepuce or frænum; but, on the other hand, a sore on the glans is more disposed to give rise to hæmorrhage, a circumstance you would be led to expect from the nature of its texture. What is

termed *phymosis*, is an inflammation, a thickening, and a contraction of the extremity of the prepuce, rendering it impossible to draw it back so as to uncover the glans: this case is less frequently a consequence of the Hunterian chancre, than of some other primary sores on the penis. My own experience does not incline me to adopt the opinion, that the hard cartilaginous base of the Hunterian chancre is essential to a sore, that is capable of imparting to the system such effects, or secondary symptoms, as are exclusively regarded as syphilitic. All surgeons know, that the Hunterian chancre may, and often does, give rise to secondary symptoms; but there are other kinds of primary sores, which will produce similar complaints, so similar that they cannot be discriminated. Therefore, I do not adopt the doctrine that none, but the true Hunterian chancre, will give rise to true venereal secondary symptoms.

Another kind of primary sore is that which is generally called the *superficial ulcer with raised edges*; it is not accompanied by induration, but its margin is very high; it is often seen on the outside of the prepuce; and frequently is not a single sore, but is accompanied by others of the same nature,—sometimes by two, three, four, or more. In many instances, you will see them surrounding the orifice of the prepuce, producing a thickening of it and phymosis, which may continue long after the cure of the sores. Sometimes you will notice some of these superficial ulcers on the corona glandis, and others under the prepuce, or around its orifice, or just on the outside of it. These sores are frequently very obstinate, and it may be long before you can make any impression upon them, whether you give mercury in full quantities, or merely in alterative doses. Sometimes in five or six weeks there will be very little change in them whatever you do, and what change does take place may be for the worse. I have seen thousands of them in my lifetime; but, I have observed, that, after five or six weeks, they generally yield to common treatment,—to mild alterative plans, namely, to small doses of mercury, aperient medicines, and antimonials, and sometimes to tonics, bark, sarsaparilla, and the mineral acids. At first, you will be discouraged by finding them resist all plans of treatment. One common situation for such a sore is just at the side of the frænum, and then the frænum is generally destroyed. The black or yellow wash, and lotions of the sulphate of copper, or zinc, are the best applications.

Another description of primary sore is the *phagedænic*, as it is termed, a corroding ulcer without granulations, corresponding to the description, given in a former lecture, of phagedænic sores in general. The primary phagedænic sore is also destitute of any remarkable degree of surrounding induration, but frequently its circumference is of a livid-red colour. This kind of sore is invariably rendered worse by mercury, a fact, which I deem

to be as well established as anything yet made out, with regard to the treatment of venereal complaints. At all events, I have never seen mercury answer in phagedænic ulceration. Sometimes in this form of disease, when the treatment is injudiciously conducted, the whole of the penis will be destroyed in a very short time. Sometimes considerable hæmorrhage takes place, and a useful hint is afforded by the circumstance; for, you will commonly observe, that, after an attack of hæmorrhage, the extension of the ravages of the disease stops, or is suspended for a time; and hence you may infer that venesection will frequently be useful in the early stages of the disease, a truth, confirmed by the experience of some of the most able observers.

Another primary sore is called the *sloughing ulcer*. It appears first as a black spot, which increases, and is thrown off, leaving exposed to view a corroded or phagedænic surface. After the slough has separated, an ulcer remains of a painful character, with a dark blue, or livid crimson margin. In this manner the disease will go on alternately sloughing and ulcerating, sometimes till nearly all the external parts of generation are destroyed. I adverted the other evening to the idea, expressed by Mr. Carmichael, that phagedænic primary sores had their origin from a specific poison, and I then mentioned to you some circumstances adverse to this doctrine; amongst other things, I told you, that this kind of sore is not always phagedænic from the beginning, which we should naturally suppose would be the case, if it arose from a specific poison. The causes of phagedænic ulceration may frequently be traced to the condition of the individual's health; to his having neglected to restrict himself to proper regimen; to his having been guilty of excess, or to his having neglected some other kind of primary sore in its commencement. The opinions I have delivered on primary phagedænic sores derive considerable support from the observations of Mr. Travers. In St. Thomas's Hospital it is known that phagedænic venereal ulcers, of a particularly severe character, are very common cases, and many of them are observed to be brought into that hospital from a particular district of the town, namely Swan Alley, near St. Katherine's Docks, in consequence of which the disease is familiarly known in the Borough hospitals by the name of the *Swan alley sore*. I have seen the same disease in St. Bartholomew's, brought, I believe, from other alleys. The genuine form of it, however, as described by my friend Mr. Travers, is usually seen in very young girls, who reside near St. Katherine's Docks, and have frequent connexion with sailors, Lascars, and other men of colour. It usually shows itself in the cleft of the nates, in the groin, or on one of the labia towards the perineum, and, as it enlarges, the surrounding skin puts on a crimson colour; its surface is generally covered with a deep ash-coloured slough; it often extends with alarming rapidity, producing great constitu-

tional disturbance and intense pain; the appetite is lost, and extreme prostration of strength attends the disease throughout the greater part of its course. It is observed in St. Thomas's Hospital, that this kind of sore is rarely or never followed by secondary symptoms; a fact, agreeing with my own observations, and confirming the view I have taken, that this sore does not depend on a specific poison, but is in a great measure accounted for by the state of the health at the time it is contracted. You will learn from Mr. Travers's statements, that most of the young creatures, who are brought from that genteel place, Swan Alley, afflicted with phagedænic ulceration, have had very little wholesome food; they are generally kept by Jews and Jewesses, who officiate as the bawds on these occasions, and who give them plenty of gin, but little proper nourishment. They are kept half starved, and more or less in a continual state of excitement and intoxication, and have connexion with Lascars, and other dirty foreign seamen, as many times in the day as there are hours (*a laugh*). I need not tell you, gentlemen, that their constitutions must be in a very disadvantageous state for the favourable progress of any disease whatever, and you cannot wonder that their impaired, imperfectly developed frames, their course of life, and uncleanness, should promote phagedænic ulceration, and give it an unusually severe character.

If proper treatment be not delayed too long, however, you will generally be able to stop the progress of the disease, but if the case be neglected, or wrongly treated at first, the ulceration will often make such havoc, as to destroy all the soft parts, closing the lower aperture of the pelvis. I have seen cases whose severity has been to this extent, and then of course the result has been fatal. I have already given you my opinion, that phagedænic ulceration does not necessarily depend on a specific poison; but, I would not wish you to imagine, that it is my meaning, that sores, originally excited by the venereal virus, are not convertible into phagedænic ones; on the contrary, I believe, that any sore may assume the phagedænic character in particular states of the health, or in consequence of bad treatment, and that in the greater number of phagedænic sores, there is no specific poison concerned at all in their production, and never essentially as a cause of them. With respect to primary venereal sores, you should be careful not to confound with them several common complaints which cannot even be suspected to be connected with, or to originate from, any kind of virus, as for example, the disease called *herpes preputii*, which begins with heat and itching of the foreskin; and, in one or two days is followed by red patches as large as a silver penny, on each of which you may remark five or six small vesicles, which lose their transparency in a few days, and become filled with pus. They then burst, and the fluid oozing out of them, and drying;

forms scabs. If you recollect these circumstances, you will not confound herpes preputii with any truly venereal complaint. *Excoriations of the corona glandis* too, and of the prepuce, are common in individuals who are not cleanly; and who neglect to wash these parts occasionally. Under such circumstances, troublesome excoriations will be likely to be produced by the lodgment of the natural mucus, and its becoming acrid and irritating. These cases merely require cleanliness for their cure. Patients with such excoriations will often ask your advice, and, if you give them mercury, you will give it unnecessarily; nothing is required but a weak solution of the sulphate of zinc, or a lotion of rose water and subcarbonate of potash. You will also see cases in which there is a scaly appearance of the prepuce, a kind of *psoriasis*; but it is merely necessary to mention this, and the other complaints, to make you aware that such cases do occur, and to put you on your guard against confounding them with true venereal sores.

Gentlemen, I shall not dwell on the plan of removing a chancre by excision, a plan adopted by the old practitioners. Sometimes they cut the sore completely away; in other instances, they destroyed it by means of caustic. The latter practice is occasionally followed at the present day, when the chancre is of small size, and this is done in order to lessen the chance of secondary symptoms, but I do not believe that much good results from the method; for, generally, when caustic is used, practitioners, do not venture to omit mercury, and when the chancre possesses the venereal character, mercury is given just as if the caustic had not been employed at all. Whether it has any influence in diminishing the risk of secondary symptoms I cannot undertake to say. If the sore be small you may use it if you please, but you should not trust to it alone. I have already told you, that all chancres are not to be treated alike. In phagedænic ulceration mercury is improper; the right plan at first is the soothing one; antiphlogistic treatment will be proper, and, if the patient be not too far reduced, and manifest traces of inflammation be present, venesection, saline antimonial medicines, and anodynes, such as conium, hyoscyamus, or the acetate or muriate of morphia, with low diet, and plenty of ventilation, and strict cleanliness will form the best plan of treatment. Then to the ulcer itself, it will be useful to apply lotions, containing opium or hyoscyamus. Quietude in the recumbent position is of course an essential thing. But in that kind of phagedænic ulceration, which I have adverted to, as seen in St. Thomas's Hospital, and which is the worst form of the disease, you should begin by enforcing a particular diet: that which is found to answer best in St. Thomas's, according to Mr. Travers's account, consists of fresh eggs and milk; there is generally great debility present, and therefore the regimen must not be too low. You

begin, then, with putting the patient on a diet of eggs and milk, and when the stomach has acquired more power, the patient may be allowed a mutton-chop every day, and from ten to twelve ounces of wine. Poultices, made up with an aqueous solution of opium, will have a good effect, and sometimes, when the sloughs are particularly firm and adherent, the nitric acid may be applied every three or four days. In other instances a lotion, consisting of a pint of distilled water, three drachms of the chloride of sodium, and one drachm of caustic potash may be employed; this will be found to produce a cleaner surface, and to promote the separation of the sloughs.

With respect to the treatment of the primary sore, characterised by a cartilaginous hard base and margin, the Hunterian chancre as it is called, I have no doubt, gentlemen, that here the proper plan is the employment of mercury; all surgeons agree on this point; but there are differences of opinion as to the extent to which mercury should be carried. Some of those surgeons, who are decidedly against the free exhibition of mercury in other primary venereal sores, are strong advocates for it in the example now under consideration. Mr. Carmichael is one of this number, and, though he cannot be said to be an admirer of the copious administration of mercury generally, he recommends a full course of mercury for the Hunterian chancre. As far as my own experience enables me to judge, I should say, that mercury is certainly called for in this species of primary sore, the disease is cured by it sooner, and it lessens the chance of secondary symptoms more effectually than any other known plan. I would give it so as to affect the gums, and produce a mild degree of salivation, but would avoid bringing on a more violent action of the mineral on the system, such as would occasion severe derangement of the health, by which the cure would be more likely to be retarded than quickened. At all events, I advise you first to try what the moderate action of mercury will do, aided by a proper regimen, before you subject the patient to a violent and profuse salivation.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE III.

Pathology and Treatment of Diseases of the Digestive System.

GENTLEMEN,—The consideration of the pathology and treatment of diseases of the digestive system shall occupy our attention to-day. I shall commence with the study of gastritis, and to this subject I would entreat your undivided attention; not that I have any thing very new to communicate, but because I

believe that many of the statements, which are connected with this disease, will be found to rest on the basis of fact and truth, many of them will be found useful in your future practice, and this subject I fear is not sufficiently considered in the schools of medicine of this and the sister countries.

The older authors described gastritis as occurring under two different forms, one of which they termed *phlegmonous*, and the other *erysipelatos*. The advanced students know the meaning of these terms, and that they are admitted as significant of different modifications of the inflammatory process, but to those, who are not advanced, I shall state, that it is very difficult to give an accurate idea of these terms, so far as they are applicable to cases of internal disease. But we may attempt a general definition by saying, that phlegmonous inflammation occurs in a good constitution, and under favourable circumstances, that it is an inflammation of a bold and distinct character, requiring and admitting of depletion, and, like that on the external parts, terminating in healthy suppuration, or adhesion. Erysipelatous inflammation is, (described to be,) a disease of a different kind, occurring in bad and debilitated constitutions, and under such circumstances that the same treatment, employed in the phlegmonous form, is more or less inadmissible; and when stimulants are necessary, if not in the commencement, at least at a very early period of the disease. It is quite impossible to found any system of pathology on this division into phlegmonous and erysipelatos; we are, however, sometimes obliged to make use of it for want of a better. The terms themselves are highly calculated to mislead. *Healthy inflammation*, which is all but a contradiction in terms, may occur in a debilitated constitution, and *erysipelatos* in a strong one. The latter of these, too, is particularly erroneous, as we now know that erysipelas may occur under opposite circumstances. In the one case, requiring the lancet and leeches, and purgation; in the other, demanding a stimulant and tonic treatment. In speaking of gastritis I do not intend to adopt this division, because it would be likely to embarrass you, and, in truth, it is unnecessary, as there is no difference in the (principles of) treatment, whatever may be the form of this inflammation. The proper way to consider gastritis is to look upon it as a disease, presenting, on the one hand, symptoms of extreme violence and urgent danger; on the other, feebly shadowed out by the phenomena of ordinary and slight indigestion. Between these there are many shades and numberless gradations. The phlegmonous gastritis of the old authors implied a violent and extensive inflammation, in which all the coats of the stomach were implicated, but in treating of the subject of gastritis in these lectures, I shall only allude to inflammation of the mucous membrane and glandular apparatus of the stomach. The other tissues are sometimes

engaged, but the mucous membrane, constituting the most important of these tissues, and forming an exquisitely delicate vasculo-nervous expansion, is, in the great majority of cases, the principal seat of inflammation, and to this I would direct your particular attention.

The true pathology of gastritis was but very imperfectly understood by the ancients. They knew enteritis and gastritis as intense inflammations of the coats of the stomach and intestinal canal, accompanied by violent pain and fever, but they had no conception of their various shades and modifications. For a knowledge of the true nature of gastritis and of its numerous varieties, we are indebted to modern pathology, and it is the boast of pathological anatomy to say that, in this instance, its labours have shed a broad and vivid light on a class of diseases previously involved in deep obscurity.

It has been stated, that it is impossible to separate the symptoms of gastritis from those which characterise enteritis, and the reason given for this is, that the two affections frequently co-exist. This is a proposition of vast importance. It is said, that in cases where you have gastritis, the chances are that there is more or less of enteritis, but according to this doctrine, if a man has gastritis the probability is, that he has inflammation of some other portion of the intestinal canal. Broussais, in the 138th proposition, makes the following observations;—"Inflammation of the stomach, or as it is called gastritis, is never found except in conjunction with disease of the small intestine. It is better, therefore, to give it the name of gastro-enteritis; and even in those cases, in which we have enteritis, we have gastritis as the irritative." Now if this proposition is true, it is one of very great importance, and entitled to a large share of our attention, in studying the phenomena and treatment of inflammation, affecting the digestive tube. Pathology, however, has proved that these inflammations are not always found in connexion. Andral gives many cases, in which disease existed separately in one or other portion of the intestinal canal; when it was found in the stomach and not in the duodenum or ileum, and when it was found in the ileum, but not in the duodenum or stomach. I myself have seen many examples of gastritis without disease of any other part of the digestive tube, and disease of various parts of the digestive tube without the co-existence of gastric inflammation. But I believe the proposition is generally true, particularly in cases of fever, in which you have secondary inflammation of the digestive tube during the course of the disease. When inflammation attacks the intestinal mucous surface during the progress of a fever, you will, in most cases, have these two diseases combined; the patient generally presenting symptoms of gastritis, and, at the same time, symptoms of enteritis affecting the lower third of the ileum.

Let us now proceed to investigate the ph

nomena which characterise acute gastritis. Here I must remark, that as an idiopathic disease, acute gastritis is extremely rare. This is a very curious circumstance. When we compare the stomach with other viscera, we shall find that one of the most remarkable differences between it and other organs is, that it is much less liable to be attacked by violent inflammation, as an idiopathic affection. This is an interesting fact. So rare, indeed, is the violent form of gastritis, that our knowledge of the symptoms which indicate intense gastric inflammation is principally drawn from the study of cases of acute gastritis caused by swallowing corrosive poisons. We very seldom meet with an inflammation of the stomach, presenting those decided characters so frequently witnessed in similar affections of other organs. We may attempt to explain this fact, by considering what the functions of the stomach are, and by recollecting, that it is the organ of the body, whose functions require that it should be most frequently in a state of great vascular excitement. Every one is aware, that the vascularity of the stomach is amazingly increased during the act of digestion; but it is to be remembered, that this is a physiological and not a pathological condition. If the stomach were as liable to inflammation as other organs, it could no longer carry on its functions with safety; every meal would prove a stimulus sufficient to excite inflammation—every digestion would be followed by gastritis. Nature has provided against such accidents.

Let us take a brief review of the symptoms of acute gastritis:—intolerable thirst, desire for cold and acidulated drinks, constant nausea and vomiting, pain and burning sensation of heat about the stomach, and fever—these are the symptoms of a violent gastritis. It has been stated, that in gastritis the fever is at first inflammatory and afterwards typhoid. If authors mean by this, that the patient rapidly falls into a low typhoid state, the observation is true. There is no form of inflammation, except that which accompanies severe peritonitis, in which the typhoid state comes on so rapidly. Inflammations of the digestive tube differ, in general, from similar affections of other organs, chiefly in this—prostration rapidly supersedes excitement. A patient labouring under inflammation of the brain will exhibit, for a long time, decided symptoms of high excitement, and of what has been termed the *phlogistic diathesis*; acute pneumonia and inflammatory affections of other parts will go on for days, without prostration, and require the use of the lancet; but gastritis is a disease in which the inflammatory symptoms, as they are called, last but for a very short time. In violent cases, the irritation of the stomach is excessive, and every thing is rejected. I have seen cold water thrown up almost immediately; I have seen effervescing draughts rejected the moment they were swallowed, and make the patient evidently worse. The epigastric region and the left hypochondrium are exquisitely

tender on pressure, and the tenderness differs from that of peritonitis in this, that it is almost always localised. The patient screams with agony when you touch the epigastrium, but will bear pressure freely on the lower part of the abdomen.

Now, with respect to the sympathetic relations of gastritis, I have to remark, that they are very numerous. First, as to respiration—it is extremely quick and hurried; the heart, also, is violently excited; and hence gastritis has sometimes been mistaken for pneumonia and pericarditis. Sometimes we have bronchitic cough; the patient is restless, gets no sleep, and is extremely uneasy; his skin is hot, his bowels confined, his pulse rapid and small. In the second stage, he is beginning to sink, his features become contracted, his skin cold and pale, his extremities sunk below the natural temperature; he now bears pressure; the vomiting is changed for regurgitation of every thing he swallows; low delirium supervenes, and he dies.

It is of the greatest importance to attend to the sympathetic relations of gastritis, for this reason, that, in many cases, the local symptoms are all but wanting, and the disease is only to be known by its sympathetic relations. Before I enter on this subject I shall make one or two remarks on some symptoms, which have not been attended to by many practitioners. One of these is an incapability of swallowing, sometimes so great, that all ingesta, whether fluid or solid, are rejected. This will sometimes arise from spasmodic stricture of the œsophagus or cardiac orifice of the stomach; and, as there has been no other cause revealed, by dissection, in several cases in which this symptom was present, we must admit this as one of the causes of the dysphagia, which, on some occasions, attends gastritis. This symptom is most commonly accompanied by tightness, and oppression about the præcordia. The patient, feeling a load or weight, as he expresses it, in this situation, thinks it would be relieved by vomiting, and begs his medical attendant to give him an emetic, which is sometimes administered, and produces very bad effects. There is only one case in which an emetic can be given in gastritis, and that is, where indigestible or irritating substances in the stomach give rise to irritation, and when we cannot expect a favourable termination, until we effect their removal.

There is another most disagreeable and distressing symptom, generally occurring in cases in which there is inflammation about the cardiac orifice of the stomach,—I mean hiccup. Hiccup is a most harassing symptom; it does not allow the patient a moment's rest; in his brief and uneasy slumbers he is conscious of it, and is constantly awakened by it. Now, this is also one of the results of gastritis, with inflammation about the cardiac orifice. I say this, because I have seen it in many cases, in which there was distinct evidence of inflam-

mation about the cardiac orifice of the stomach; and, in three instances, I have verified it by dissection. I do not mean to say, that every case of hiccup is indicative of disease of the cardiac orifice, but I believe it is a very frequent accompaniment. The case of a celebrated professor of languages was a remarkable example. A short time previous to his death, he came from Liverpool in one of the steam packets. He was always subject to sea sickness; but on this occasion, he was extremely ill, and vomited during the entire passage or sea-voyage. He complained of his stomach for some time, and then got hiccup, which resisted every kind of treatment, and continued without any abatement up to the time of his death. On opening the stomach, this organ was found in a state of intense inflammation, particularly about the cardiac orifice. You can see the stomach (of which a very good preparation has been made by Dr. Houston) in the museum of the College of Surgeons. There was another very remarkable case in the Meath Hospital. A patient was admitted who had laboured under acute pneumonia, for which he was treated with tartar emetic, and the symptoms rapidly declined, but vomiting and hiccup came on, and the latter symptom continued until death. We opened the body eighteen hours after his demise, and found the lung quite healthy; but the stomach, and the cardiac orifice in particular, were, as in the case I have just mentioned, in a state of intense inflammation. When hiccup is the result of inflammation of the cardiac orifice, you will also frequently observe, that the patient complains of pain in the lower part of the chest, along the course of the diaphragm. These are some of the relations of gastritis, their connexion with which is proved by their being relieved by draughts of cold water, leeching, and every other means calculated to remove inflammation of the stomach.

We come now to consider the state of the tongue. A vast deal of error and misconception prevails among British practitioners on this subject. Nothing is more common, than from the condition of the tongue, to form an opinion as to the state of the alimentary canal. For instance, whether it is in a state of inflammation, whether there are sordes present or not, and whether it requires this or that medicine. All this is behind the actual state of medicine, and it is melancholy to think, what a vast quantity of mischief is done by those practitioners who take the tongue as the index of an inflammatory or non-inflammatory condition of the intestinal canal. The schools of Abernethy and Broussais are wrong in stating that the tongue will point out the state of the digestive tube. The connexion between the state of the tongue and that of the stomach, has been lately made the subject of extensive clinical investigation by M. Andral; listen to his sentiments on this point. From the experience of a vast number of cases, he declares, "that there is no constant relation between the

state of the tongue and that of the stomach." In the next place he states, "that there is no modification of the one corresponding with any special modification of the other." "Thirdly, the stomach may be found in a certain state after death, with various conditions of the tongue during life." "Fourthly, we may have a diseased stomach with a healthful condition of the tongue, and diseased appearance of the tongue, with a healthful state of the stomach." These are facts of the greatest importance. Let us now refer to Louis. In giving an account of the gastritis which accompanies fever, he states, that in many of the worst cases the appearance of the tongue was natural, in fact, that there was not the slightest relation between the tongue and the stomach. It is fair, however, to observe here, that both these pathologists drew their information only from cases of gastritis, occurring in fever. But it has also been frequently observed, that even in idiopathic cases, there is a want of correspondence, between the condition of the tongue and stomach, and we have seen several instances of this in the Meath Hospital. I believe we should be wrong in taking the tongue alone, as our guide, in the treatment of intestinal derangement, whether existing in the stomach or any other portion of the tube, and this I state, as the conclusion which I have drawn from my own experience, in gastric and enteric inflammation. Yet how many will you see taking the tongue as the unerring index of various conditions of the digestive tube? hundreds and thousands. It is unquestionably true that in certain cases of gastritis, particular morbid appearances, as redness, dryness, pointing, and a tremulous state of the tongue, are observed, but what I wish to impress on you is, that it is *necessary that these phenomena should coincide with other symptoms*. I do not wish you to believe, that the inspection of the tongue, or the knowledge derived from its appearances, is useless, particularly in cases of fever: the state of the tongue is never to be overlooked, but you should understand on what principle it is to be examined. You should examine the tongue not so much as a guide to the knowledge of local disease, but *as an index of the condition of the general system*. For instance, if during the course of a fever, the appearance of this organ changes and becomes more favourable, it is a sign that the whole disease has taken a favourable turn, and vice versa. This is the proper way to look at the tongue in fever, not as reflecting any particular state of the intestinal canal, but as being indicative of some modification of the whole economy.

Let us now consider the sympathetic relations of the nervous and respiratory systems in gastritis. This is a very curious and interesting point in the study of gastric disease. I may mention here, that these relations are subject to considerable variety, and differ according to the peculiar predisposition of the individual. If a person of nervous habit gets

gastritis, he will be very liable to have sympathetic affections of some part of the nervous system; but if he is a person with unsound lungs, the irritation will be transferred to the respiratory apparatus. Can we define these irritations? I believe the best definition we can give of them is, that they are affections of some organ, which are the result of sympathy; and that they are at first functional, but afterwards become organic. A person of nervous habit, labouring under gastritis, will frequently have his head sympathetically affected; he will complain of headach, more or less intense; toss about and get no sleep; still he has no actual disease of the brain. But let the cerebral irritation go on, let the pain and uneasiness and watchfulness continue, and he will finally get arachnitis. So, too, with respect to the lung; the patient has hurried breathing and cough, without any of the stethoscopic signs of pulmonary disease; but if these symptoms continue for any length of time, or if the irritation be severe, he will get pneumonia or bronchitis. Observe the importance of this law with reference to treatment, because it shows you that you cannot always expect to remove sympathetic affections by attacking the original source of disease; for if functional derangement, produced by sympathetic irritation, has gone so far as to become organic; you must direct your attention to parts which have been secondarily engaged, as well as to those which are primarily affected. Every one is aware of the effects of particular states of the stomach on the brain, and of the influence which the brain exercises over the stomach. Most individuals know, that by grief or strong mental emotion the appetite is completely removed; and that after a surfeit, or from taking bad and indigestible food, a person will get sick headach. If this happens every day under ordinary circumstances, and where the original affection is so slight that it does not interfere with the usual avocations of the patient, you can readily conceive how intense the sympathetic irritations may be in a case of violent gastritis. The headach is frequently intense, the patient is extremely restless, there is considerable intolerance of light, delirium, tetanic spasms, and other symptoms characteristic of inflammation of the brain. There are numerous cases on record in which these symptoms were particularly noticed, and it was supposed that the brain was in a state of inflammation, but on dissection there was no disease found, except in the mucous membrane of the stomach. There are many cases, too, in which medical men, not aware of the extent of these relations, looked upon the disease as a pure cerebral affection, and directed their whole attention to the brain. They certainly succeeded in modifying the apparent disease, but as they took no steps to remove its cause, the patients generally sunk from an unsuspected gastritis. There is one important law with respect to inflammation of the stomach, which perhaps

may be fairly applied to all inflammatory affections of the digestive tube. When inflammation of the stomach or any other portion of the intestinal canal has continued for some time, and when the disease has attained a certain degree of violence, the local symptoms may subside, and the gastritis or enteritis will be represented by disease of some other organ, by symptoms of an affection of the brain or its investments, or by symptoms of disease of the lining membrane or parenchymatous tissue of the lung. I shall endeavour to explain this. Here is a case taken from the *Clinique Médicale* of Andral.

"A middle aged man, four days before his entrance into the hospital, was seized with bilious vomiting, epigastric pain, and fever. (Here is a certain case of gastritis.) In about twenty-four hours after the invasion of these symptoms, he first perceived a difficulty in depressing the lower jaw, and a violent trismus was established, which continued for the two following days, at the end of this time, he entered the hospital in the following state:—trismus, the head drawn backwards and forcibly retained in this position by the muscles which are inserted into the occipital region; rigidity of all the extremities; abdomen hard as a board; intellect perfect. Notwithstanding the trismus, the patient could articulate with sufficient distinctness to give the above account of his case. *From the time when the first tetanic symptoms appeared the vomiting and epigastric pain ceased.* He died on the evening of his admission. On dissection no appreciable alteration of structure was found in the brain or spinal marrow; the meninges of the brain were very slightly vascular, but those of the spinal marrow pale. The whole surface of the stomach presented an intense red colour, which was at first concealed by a thick layer of mucosities. The remainder of the digestive tube was perfectly healthy, and the thoracic organs were natural." This may be called a case of tetanus; and it is a curious fact, that when the tetanic spasms came on, the vomiting and other symptoms of gastritis subsided. Now this is what I wish to direct your attention to. A man dies with symptoms of an affection of the brain, the head is opened after death, there is no trace of cerebral disease found, but the whole surface of the stomach is discovered to be in a state of intense inflammation. That the stomach was inflamed is proved by the vomiting and epigastric pain which existed during life, as well as by the vascularity which was revealed by dissection; and there can be no doubt that this condition was the result of an intense inflammation, as there was no other cause to produce it.

Last year, a patient was admitted into the Meath Hospital, labouring under violent maniacal excitement, his eyes blood-shot, and his aspect ferocious. He had thirst, a dry fissured tongue, a quick weak pulse, and constipated bowels. There was no epigastric tenderness,

no vomiting, in fact, none of the prominent symptoms of gastritis complained of. On the third day, the belly was slightly tender and tympanitic. The cerebral symptoms increased so as to require the use of the strait waistcoat, and continued with violence until a short time before death, which occurred on the eighth day. On dissection there was no appearance of inflammation found in the brain or its membranes, but there was a vast extent of disease in the digestive tube. The splenic extremity of the stomach presented several patches of vascularity, and its mucous coat was softened; the lower half of the ileum, the cæcum, and part of the ascending colon were in a state of intense inflammation, and dotted all over with numberless ulcerations.

You observe of what importance the knowledge of these facts will be to you in practice, and how much it should become the object of your study, since you will thereby be able to make the diagnosis of gastritis from the sympathetic relations, though the usual symptoms are more or less absent. Even in cases of this kind, in which the symptoms have subsided on the appearance of these sympathetic irritations, the judicious practitioner will not be diverted from directing his attention to the source of the original mischief; nor will he, because the local symptoms have disappeared, conclude that the disease has therefore been removed from the stomach. Many examples of this *apparent* transition of disease are to be seen in cases of children, in which an inflammation of the upper part of the digestive tube frequently simulates hydrocephalus, and where the headach, delirium, and intolerance of light are completely removed by the application of leeches to the epigastrium. I have seen this occur many times, and would entreat your particular attention to it. I believe many children are lost from the want of correct notions on this subject on the part of their medical attendants. The phenomena present in such cases ~~are~~ certainly those which characterise hydrocephalus; but you should always investigate them with care, and ascertain whether the disease has commenced with symptoms of inflammation of the mucous membrane, of the stomach, or bowels; and if you find that it has originated in this way, and that the cerebral symptoms have not gone too far, direct your treatment in the first place to the digestive tube. It is extraordinary how rapidly all the symptoms of apparent cerebral disease subside under this plan of treatment. I must mention here to you a very remarkable case of enteritis, which simulated local disease of the substance of the brain. A girl who had received an injury was admitted into the Meath Hospital; she was treated with purgative medicine, and was "*discharged cured*." In a few days afterwards she was re-admitted with pain in the head, and violent spasmodic contractions of the fore-arm, by which the fingers were bent so forcibly that the nails were driven into the

hand. There was no thirst, vomiting, or abdominal tenderness. She died a few days after her admission; and on dissection the brain was found perfectly healthy, the viscera of the thorax were in the normal state, the stomach presented nothing remarkable, but the ileum was almost one sheet of deep and recent ulcers. The result of this case is important also in another point of view. You know that spasmodic contractions of the upper extremity are believed by certain pathologists to point out an inflammatory softening of the optic thalamus, and its prolongations. Here we had the symptom, at all events, without the corresponding lesion.

I shall reserve the subject of sympathetic irritations of the respiratory system until Wednesday, when I expect to be able to finish the pathology and treatment of gastritis.

CLINICAL LECTURES

DELIVERED

At the Meath Hospital, or County of Dublin Infirmary, Session 1833-34.

BY PHILIP GRAMPTON, M.D., F.R.S.,
Senior Surgeon to the Meath Hospital, Surgeon-General to the Forces in Ireland, &c.

LECTURE IV.

Treatment of Compound Fractures of the Extremities.

GENTLEMEN,—In treating so large a subject as compound fractures of the extremities, it will be convenient to adopt something at least approaching to a classification of these injuries; I shall accordingly divide compound fractures of the extremities into two classes; the first will include those injuries which may from the nature or extent of the lesion be considered as incurable, and which consequently require the sacrifice of the wounded limb in order to afford the best chance of preserving life. The second will include those injuries which are deemed curable, and which consequently are proper subjects for a methodical treatment. This, it is obvious, is a very imperfect classification, as it is grounded on our knowledge of the resources of nature, which must always be imperfect, and our confidence in the resources of art, which is often misplaced. Accordingly every day furnishes us with instances of limbs which have been condemned to amputation having been perfectly restored by the mere powers of the constitution, unaided, or (it may be) obstructed by the interference of art; and on the other hand we have but too often to deplore the error of judgment which determined us to attempt to preserve a limb, which the result has proved should have been sacrificed. In this uncertain state of the art, all that can be done in the way of arrangement is to place in one group all those injuries, which in the judgment of the most experienced surgeons are thought to be incurable, and in another all those which, however dangerous, are considered as proper subjects for surgical

treatment. The great question of amputation (as it is called) turns on this classification.

It is true, however, that this question must be often determined by other than purely surgical considerations. There is, for instance, infinitely more danger to life in conveying a man with compound fracture ten or fifteen miles, for several successive days, in a rough carriage, than in amputating the limb; hence in military practice it is often advisable to amputate limbs which in civil practice would be considered as curable. The lesions, however, which even under the most favourable circumstances, may be considered as incurable, and which consequently require the amputation of the injured limb, are,

First, when a part of the limb is shot away; here amputation above the shattered bone, or generally above the articulation connected with the truncated limb is indispensable. Secondly, where the soft parts are extensively lacerated, and the bone broken into small fragments; as when the limb has been crushed by machinery, or by the passing of a heavy carriage over it. Here, at the best, you must expect profuse suppuration, tedious exfoliations, and hectic fever, which will ultimately run the patient down, even if he should escape the gangrene which usually attacks limbs under such circumstances within the first few days. In the third place, where, in addition to the injury done to the bone, the soft parts are crushed and their texture destroyed, even though the skin should be unbroken. A spent cannon shot, brushing against a limb obliquely, will often fracture the bone, and reduce the soft parts to a black, pulpy, disorganised mass, without wounding the integuments. Fourthly, where a large portion of the soft parts has been carried away, and the principal nerves and blood-vessels divided. When a large piece of the leg or thigh, for instance, is shot or torn away, and the nerves and blood-vessels injured, it is not only useless, but in the highest degree dangerous, even to attempt to preserve the limb. Fifthly, when the artery and vein are cut across by a ball, even though the bone should have escaped. Sixthly, when the bone is fractured with division of the principal artery; provided, however, that the wound be inflicted by gun-shot, for if it be done by a cutting instrument, or be the result of a punctured or even lacerated wound, the limb may be saved by tying the artery. Thus a man falling from a height on spikes may get his thigh broken, one of the spikes entering the flesh, may open a large artery, yet this may not be a case for amputation. Seventhly, when a musket-ball enters or lays open a large joint, tearing the ligaments and fracturing the head of one or both of the bones, this is a clear case requiring amputation. But if the fracture be an oblique one, about two or three inches from the joint, even though it should involve the head of the bone, it is not necessary to remove the limb, *if the injury be not inflicted by a musket-ball.* I have seen many instances

of this kind do well, and there is a case at present in Meath Hospital of compound fracture passing into the elbow joint, which in all probability will terminate favourably. A fracture through the head of the bone, with a wound communicating with the joint, made with a clean cutting instrument, is not a case for amputation; for you are aware that the operation of cutting into the knee-joint, for the extraction of loose cartilaginous bodies, is frequently performed with success, and wounds of the ankle-joint, made with a sharp instrument (as with a scythe) often do perfectly well. The first case which I saw of a penetrating wound of the ankle joint was a very remarkable one. The subject of it was a young man of the name of Stephens, a chandler, who lived at that time in Bride Street, at the corner of Bull Alley. When cutting a cake of greaves with an adze, he missed his blow, and sent the edge of the instrument directly through the ankle joint, cutting off the extremities of the tibia and fibula, which form the inner and outer ankle. The heel drawn upwards by the flexors exposed the joint completely. The anterior tibial artery bled freely, but the bleeding had been in some degree suppressed by the pressure which the young man made on the wound with his hand. I accompanied my late lamented friend and master, Mr. Richards, to visit the case, and here received my first and best lesson in surgery. The artery being secured at both ends with a single silk thread, the wound was brought into perfect apposition, and the skin was kept together by three points of the interrupted suture. Pledgets of lint, dipped in a kind of paste, formed of white of egg and flour, were laid over the wound. The limb was kept securely in a proper position by lateral splints and a foot piece, a strict diet was enjoined, and the dressings were not touched for three weeks. At the expiration of that period the splints and bandage were removed, and it was found that the wound was completely united. The accident occurred in the year 1798, and I had the pleasure of meeting the subject of it very lately walking stoutly along the Rathfarnham-road. He lives in the village of Rathfarnham, on the left hand side of the road, and follows at present the occupation of a brewer; he told me he would be happy to show his foot to any one desirous of seeing it. I am thus particular in authenticating this case, not only because it is a most instructive one, but because I wish to have it on record, that five and thirty years ago the principle of treating compound fracture, of wound of a great articulation, was as well understood in Dublin as elsewhere, and that in this particular at least we cannot pretend to depreciate the skill of those who immediately preceded us.

Gun-shot wounds of the thigh with fracture of the bone are in the highest degree dangerous, and the generality of surgeons, British and foreign, recommend immediate amputation in such cases. There are, however, many

exceptions to this rule, and in my own case I confess that I should prefer taking my chance without an operation, *if the ball only entered the thigh and fractured the bone without splintering its extremity* (without wounding the femoral artery or popliteal nerve), and above all, at such a distance from either of its extremities, as to make it probable that the articulation was not implicated in the wound. I do not mean to say, that by not submitting to amputation I should increase my chance of preserving my life; on the contrary, I believe I should very much increase the probability of death, but I would willingly put my life to a great risk to preserve a lower extremity.

I remember a very striking instance of a favourable termination of a wound of this kind, which occurred during the campaign in Holland, in the person of Colonel Gordon, of the 92nd Highlanders. He was an extremely fine looking man, six feet five inches in height, of a powerful frame and robust constitution. He received a shot through the thigh, nearly in the direction of the femoral artery, which fractured the bone about two inches below Poupart's ligament. In his fall the extremity of the bone was driven nearly two inches through the integuments, and the leg was drawn up by violent spasms from the irritation of the muscles. The colonel, who was a determined and sensible man, immediately raised himself into a sitting posture, and pressing the heart of the sound foot against the heel of the wounded limb, and applying his hands to the bone, he brought the thigh into a straight position, and thus endeavoured to replace the protruded bone as well as he could. The spasms, however, continuing to make the bone protrude, he took off his sash, and having adjusted the fracture as well as circumstances permitted, he tied the sash tightly round the thigh, and though some persons seeing him on the ground offered to raise him up, he refused their assistance, and remained there quietly until a surgeon came, who applying a firm splint from the heel to the hip, had him carried to his quarters. I saw him constantly during his convalescence, which took place without the occurrence of a single bad symptom. He lived many years afterwards, and was killed at Waterloo by a shot through the forehead, while leading a charge at the head of his regiment.

Such cases, however, must be considered as exceptions to the general rule. With respect to fractures of the thigh by gun-shot, individual cases (particularly where the bone is fractured at its lower third, and where it is not extensively splintered,) will occasionally recover; but the concurrent experience of all practical surgeons seems to establish the surgical principle, that in compound fracture of the thigh by gun-shot, immediate amputation affords the *best* chance of preserving life. It is a question for serious consideration, whether life should not be risked, and to a

very great extent, for the chance of preserving a lower extremity, especially as in such cases secondary amputation may be looked to with a reasonable prospect of success; but on this point I would refer you to the works of the military surgeons, and particularly to those of Baron Larrey, Mr. Guthrie, Mr. Hennen, Mr. Hutchinson, and Sir James Ballingall.

Gun-shot wounds with injury of the bones have a tendency to run into gangrene. A very few years since it was considered as against the canons of surgery to amputate in such cases, until a line of separation had been formed between the dead and living parts, and this doctrine was supported in some of the schools in this city until a very late period. The first place in which amputation was performed in spreading traumatic gangrene in this country, occurred about twelve years since in Jervis-street Hospital. The operation was performed by Mr. Wilmot, (who at that time was, as well as myself, a surgeon to that institution,) and the man recovered perfectly. It was a case of gangrene from compound fracture with comminuted bone. The operation has since been several times performed with success in this hospital, lately in a very remarkable and most unpromising case. The patient's name was West, and I had operated on him for popliteal aneurism about two or three months before. He was re-admitted with inflammation of the periosteum of the tibia, which was accompanied with high sympathetic fever, and terminated in suppuration. He then suffered from suppurating of the ankle-joint, and finally the foot was attacked with gangrene, which, in the space of two or three days, extended to the lower third of the leg. The pain now became so excruciating, that he intreated of me to amputate the limb, and said that he was willing to undergo the operation even for the sake of a few hours' respite from his sufferings. I performed the operation, and the man's recovery was rapid and complete. He is at present a wine-cooper in the employment of Mr. Kinahan, of the Carlisle Buildings.

It is exceedingly difficult to lay down any specific rules with respect to circumstances under which amputation may be performed in spreading gangrene, nor is this a proper occasion for entering on so wide a field of discussion. I would merely observe, that the chances of success in such cases are directly in proportion to the degree in which the affection seems to be local, that is to the degree in which the constitution does not participate in the injury. When the pulse, countenance, and spirits are good, you may amputate with a reasonable prospect of success, but if the powers of life are sinking rapidly, as indicated by the collapsed features, cold perspiration, weak and faltering pulse, and, above all, by an aberration of mind, the operation will inevitably only hasten the fatal result. On this subject I should wish you to consult Mr. Guthrie's valuable work on Gun Shot Wounds, and particularly Mr. Porter's most instructive paper

on Amputation in the Eleventh Number of the Dublin Medical Journal.

In determining the great question of amputation in any given case, a number of extraneous circumstances must be taken into account, which will exercise a material influence on your decision. If, for instance, a man were to suffer a compound fracture of the leg by gun-shot, under circumstances which made it necessary that he should be conveyed for several miles, on a rough carriage, before he could be laid in bed, (a case which must often occur in military practice,) it would be far better to perform amputation on the spot than to make any attempt to preserve the limb. In military practice, therefore, the question of amputation is often decided by other considerations than the mere severity, or complication of the injury.

Now, with respect to the treatment of compound fracture when curable, the indications are first, to get the bones as nearly as possible into a state of proper apposition, and if the case admits of it, to bring about union of the external wound. In order to effect the latter, you must put in practice diligently every means of keeping down inflammation. To accomplish this you must endeavour to remove the exciting causes. These are principally the irritation of spiculæ of bone, and what the French writers call the strangulation of the wound. There is nothing which so completely prevents the occurrence of active inflammation as giving free scope to parts confined and rendered tense by the swelling which accompanies active inflammation. If, therefore, you meet with a case of compound fracture, where you endeavour to reduce the projecting spicula, and find that you cannot accomplish it without employing force, in all such cases, the simple course is to pass a probe-pointed bistoury under the confining skin, and make an incision sufficiently extensive to admit of the reduction of the bone. Then make extension in the manner I have already mentioned, and you will be able to accomplish the reduction with ease. There is much more mischief done by attempting to drag the projecting portion of bone into its proper place, than by making a simple incised wound in the skin, which can be easily healed. You will, therefore, when you meet with a compound fracture of the leg, under such circumstances, first try what you can do by slitting up the skin, and when you find that you cannot reduce it in this way, you may then saw off the projecting portion of bone.

You will meet with cases in which there is a portion of bone broken off, which lies between the soft parts and the fractured extremities, preventing their proper coaptation. Here you must give plenty of room for the reduction of the fracture, and extract the loose portion of bone with your finger, or with the forceps. Then, if the tibia projects after reduction, place the leg on one of these back splints, or on the double inclined plane, which

will keep the limb in a flexed position, and prevent disturbance. Your next consideration is the dressings, and here I must say that to put even a moderately tight bandage over a limb so circumstanced is the worst thing you can possibly do. In the space of a few hours the bandage becomes tight from the swelling of the limb, and gives the patient exquisite torture. In such cases, lay the limb in the easiest possible posture; do not cover it with bandages, but place over the wound a pledget dipped in the fresh blood from the wound, or in a mixture of flour and white of egg, and apply leeches in relays of twenty or thirty at a time, followed by the spirit-wash. Keep the limb steady by a suitable apparatus; the enlargement of the wound, in case of inflammation of the fascia, is frequently very useful; you saw the great advantages which resulted from it in the case of Hogan, a woman in the accident ward, who has compound fracture of the tibia about two inches above the ankle-joint. She, I am sure, would have had gangrene of the limb if she had not been treated in the manner you have witnessed. The inflammation was allayed by repeated applications of leeches, and the tension of the parts was relieved by making an incision through the fascia.

One of the principal things which it is necessary to attend to in the management of fractures of the leg, is to prevent the motion of the foot, and, consequently, of the lower fragment. The mode in which this is effected in the French hospitals is liable to objection. It is a common practice there to fix the foot, by a cross tape extending from the foot, to each side of the bed. But if you fix the foot in this way, as often as the patient turns or moves himself, the upper portion of the bone rotates to a certain degree, while the lower portion remains fixed. To avoid this, you must confine the leg and foot together, resting on the heel on an inclined plane, or on one side with the aid of proper splints, and support it on each side by pillows, varying the position from the straight to the flexed, according to the circumstances of the case; keeping it straight when the tibia has a tendency to protrude forwards, and flexed when there is no such tendency.

I need not caution you against the use of poultices, for we seldom employ them here, because they have a tendency to increase suppuration. The only thing we use in cases of compound fracture is the spirit wash, or a weak solution of chloride of lime. During the progress of the cure, the patient's strength is to be kept up by a mild, nutritious diet, avoiding any thing which may stimulate or produce, constipation. The surgeon acquainted with the nature and course of compound fracture, will always look forward to a long confinement; and hence he will never take away a large quantity of blood from the system, whatever may be the degree of inflammation. For the last twenty years I have never drawn

blood from the system in a case of compound fracture. I know very well that a young and vigorous man might not be the worse for losing a little blood, but I believe that in these cases every good purpose may be answered by the repeated application of leeches. In the advanced stage, where there is no febrile excitement in the system, and the patient is much run down, there is a great advantage derived from the use of bark and the mineral acids. You will also effect a great deal of good by sending your patient, if possible, into the country.

There is another and a most important point in the treatment of compound fractures, viz., to make your patient comfortable in bed, a consideration essentially necessary in this as well as in all other cases requiring long confinement. By making a man comfortable, you dispose him to be quiet, and enable him to enjoy repose. The great object is, to shift him and make his bed comfortable without disturbing the fracture. If you employ the back splint I have shown you, you can raise the patient up and place him on another bed, or keep him sitting on a chair with his limb supported until his bed is adjusted: but still this mode is liable to many objections. There is more or less risk of disturbing the fracture; and sometimes the patient is so weak and nervous, that the attempt to raise him excites the utmost terror and agitation. There is a very cheap and convenient apparatus, which I have for a long time used in such cases with the greatest advantage, and which is remarkable for its simplicity. There is a great number of contrivances, of a complex nature, invented for similar purposes, of which you will find descriptions in the French Dictionary of Practical Medicine and Surgery. That which I am about to describe is a simplification of the complicated machine used at the Hôtel Dieu, and may be procured at the expense of a few shillings. Get a frame of wood of an oblong shape, six feet three inches by three feet six, and firm enough to support the weight of a man. The side pieces of the frame should project beyond it to the extent of six or eight inches. You then take a strong sheet and cut it into strips, each about eight or ten inches wide: these slips are made fast to one side of the frame from top to bottom, but at the other side they are free; and to each corner of these slips, at their free extremity, there is a strap attached, by means of which they may be made fast to the buckles fixed to the other side of the frame. To the free extremity of each of these strips there is also a pocket attached, by means of which, with the assistance of a long and slender piece of steel, somewhat like an apothecary's spatula, but broader, you can easily pass the strips under your patient when you want to change him. This machine is laid over the patient's bed, and he lies within it, like a picture in its frame. When you want to have him moved for the purpose of emptying his bowels or arranging his bed, you make

fast the strips by means of the buckles, lift him out of bed, frame and all, and having placed the machine on a proper support until the bed is arranged, you can replace him on his bed, unbuckle the straps, withdraw the pieces of linen one by one, and remove the frame without the slightest disturbance of the fractured limb. I will bring one of these machines to the hospital and show you its mode of application and use. Dr. Arnott's hydrostatic bed, however, supersedes the necessity of all other contrivances for making a sick bed comfortable; and I consider it as one of the greatest boons which science has ever conferred on suffering humanity. You have an opportunity of observing the advantages which may be derived from this admirable contrivance, in the case of the old man with the compound fracture of the elbow-joint; he had not been on the water-bed for three days when the sloughing sores on the back put on a healthy aspect, and they are now nearly healed; the wounds about the joint, too, have ceased to discharge, and I now can pronounce the man convalescent.

I have alluded before to the manner in which persons who have received fractures of the extremities should be carried home; before I conclude I shall make one more remark on this subject. The common way is to have the man taken under the arms by two persons, while a third person holds his feet, the effect of which is frequently to force the bone out through the skin, and convert a simple into a compound fracture. One of the simplest and easiest modes of carrying a person is to get a long corn sack, and two poles, or pitchforks (which may be procured anywhere), then pass the ends of the poles through two holes in the bottom of the sack, and having laid your patient on this, you can have him carried home comfortably and without danger. It will be necessary, however, that the persons who carry him should "keep the step," to avoid any inconvenient jogging motion. You may see at the Royal Infirmary, in the Phoenix Park, a machine which I had constructed for carrying wounded soldiers. It is merely a cot suspended from a frame by means of straps, which are attached to two tilbury springs, one at each end, resting on a firm piece of wood, which is supported by the cross piece of the frame. This machine may be carried by men, or it may be placed altogether in a large cart or float. The motion of the men or of the vehicle is not communicated to the cot, which is suspended from springs; and, whenever it can be procured, it will be found to be an excellent apparatus for the purpose, and fully capable of obviating those dangers which but too frequently result from an improper mode of carrying patients with fractured limbs. On the following day Mr. Crampton exhibited the machine, a drawing of which will be given in our next number.

When the lecture was concluded, a man

about 50 years of age; and of a most muscular frame, was brought into the theatre with a dislocation of the left humerus, which he stated had been caused by a fall in the street on the preceding Saturday, so that the humerus had been dislocated thirty-eight hours. Some ineffectual attempts had been made elsewhere to reduce the bone, and some blood had been taken from the right arm this morning. Mr. Crampton placed the man sitting on the floor, and having made a surgeon's knot on a silk handkerchief, he passed the patient's hand through the middle noose, and embraced the wrist in it tightly, by drawing the ends firmly parallel to each other, one on the ulnar, and the other on the radial, side of the hand. Mr. Crampton then stood on a chair, which was placed close to the patient's left side, and raised the arm slowly upwards and a little forwards, i. e. towards the patient's face, until he nearly, but not quite, raised him from the ground; in less than half a minute Mr. Porter, who kept his hands pressed into the axillæ, exclaimed,—"It is moving—it is in." The arm was then brought down slowly to the patient's side, and Mr. Crampton desired him to lay his hand on his forehead, which he did with perfect ease, and, making a good-humoured salute to the class, he withdrew.

A CASE OF PHTHISIS SUCCESSFULLY TREATED

BY E. C. WARING, SURGEON.

IN presenting to the public the following particulars of a case of phthisis, successfully treated, I need, I imagine, only briefly advert to those circumstances which render this disease an object of so great importance to the medical practitioner,—I mean its very great prevalence, and, in the confirmed stage, its almost uniform fatality.

Sydenham computed that two-ninths of all fatal cases were cases of phthisis, and if my opinion were asked, as to the correctness of this observation, I should say it was rather below than over the truth.

In reference to the latter circumstance, namely, its almost uniform fatality, I may leave it to the candour of any person, who has had even limited opportunities of observing the disease, how rare instances of recovery are, under the usual palliative mode of treatment.

A short time previously to the occurrence of the following case, my attention was directed to the plan proposed by Dr. Senter, as quoted in one of the early volumes of the

Medical and Chirurgical Review*, which, from the evidence there adduced in its favour, I thought well worthy an early trial.

John Wood, about 35 years of age, naturally of a spare habit and phthisical conformation, had been under the care of the parish surgeon for several weeks without deriving any benefit, who, at length, declared his case hopeless, and declined to administer any more medicines. It was under these circumstances that, on Dec. 5, 1832, I was requested to visit him, not with any expectation that I should be able to afford permanent benefit, but merely to relieve his sufferings, which were said to be very great.

I found him much emaciated, labouring under profuse purulent expectoration, which, I was informed, was occasionally streaked with blood; a tickling cough, pain of chest, increased on inspiration; with constant hectic exacerbations at night with drenching perspiration. He complained of troublesome dyspnoea upon using the least exertion, and that he had for several weeks continued growing much weaker and worse.

These circumstances, the hectic flush on his cheeks, and his very unfavourable general appearance, seemed to indicate that his disease would not be long in arriving at the usual termination.

Detrahuntur sanguinis uncie octo saltem; pleno rivo ad dolorem lateris mitigandum.

6th. Pain of side, which had totally disappeared after the bleeding, has returned. Cough a little alleviated by the linctus. Night sweating unrelieved.

Repetantur pulvis. h.s.s. Pergat in usu linctus, nunc in promptu.

* Published originally in the "Transactions of the College of Philadelphia," and reviewed in the work referred to in the text.

7th. Has had a bad night. Pain of side much worse, owing to the almost incessant coughing. All the other symptoms remain in statu quo.

Admoveatur empl. cantharid. parti lateris dolenti. Repetantur pulvis et linctus ut antea.

On the 7th, 8th, and 9th, with a continuance of the same medicines, he remained also unrelieved. The blister had but slightly relieved the pain in his side, and the night sweating continued unabated, as also the purulent expectoration and the dyspnoea, and his cough was as troublesome as ever, unless he continued constantly using the linctus. I therefore fell myself justified, on the morning of the 13th, in adopting a totally different plan of treatment,—the plan which I have before alluded to as being that proposed by Dr. Senter.

Pergat-in usu linctus. p. r. n.

I visited him after the operation of the emetic. It had operated, but not violently, three or four times, about half an hour after being taken. He was, as might be expected, rather hurried and overcome by the action of the medicine, but expressed himself very grateful for the removal of a sense of weight, which he had all along felt behind the sternum. The pain on inspiration also was quite gone. The matter ejected by vomit had been retained at my request. The supernatant fluid consisted of the warm water, which he had drank to assist the operation of the medicine, tinged of a bluish-green colour by the sulphate of copper, but at the bottom of the vessel was a large quantity of tough purulent mucus, together with what little food the stomach had contained: Breathes more easily and lightly; pulse frequent, as before, but more full and strong.

11th.—Much improved to-day. Cough and pain of side quite gone; no heavy expectoration or night sweat, but continues weak. Pulse much reduced in frequency (now about 90), more regular than before and moderately firm.

From this period until the 28th, it was found requisite to repeat the emetic four times, owing

to a return of the sensation of weight behind the sternum, and the other unfavourable symptoms. The character of the ejected matter improved each time, with a correspondent improvement in the state of the patient.

The cough, which had disappeared upon the administration of the first emetic, returned with each re-accumulation of pus in the lungs; at which time, also, the pulse increased much in frequency, and became contracted and rather hard, both which unfavourable symptoms were immediately removed by the action of vomiting.

His pulse continued to lower in frequency and improve in strength after the administration of each successive emetic. His appetite, bodily strength, and general appearance rapidly improved under the use of the Mist. ferri comp., the dose of which had been gradually increased, until he took twelve ounces in the twenty-four hours, which quantity he continued to take for several weeks, when he was enabled to resume his very laborious occupation, that of hand-loom weaving, and was discharged cured.

I should not omit to state, that upon the administration of the second emetic, a repetition of the dose was found necessary before it would operate; and each time afterwards, twice the quantity first prescribed was requisite.

The results of my future trials, whether successful or otherwise, shall be faithfully communicated to you.

*Charles-street, Wrexham,
Dec. 23rd, 1833.*

FATAL HÆMORRHAGE BETWEEN THE ENVELOPES OF THE EMBRYO.

BY J. T. INGLEBY, LECTURER ON MIDWIFERY AT THE SCHOOL OF MEDICINE, BIRMINGHAM.

Case of Laceration of the Chorion and effusion of Blood within the Decidua Uteri, as seen on inspection of the Body of a Woman who died suddenly near the third month of Pregnancy.

A WOMAN, æt. 36, the mother of six children, and in whom the last menstruation ceased on the 31st of August, expired very suddenly on the 14th of November, being about ten or eleven weeks advanced in pregnancy, under circumstances unusually mysterious. As re-

spects her history, I learn that she was subject to a slight degree of giddiness upon exertion, her general health being otherwise good. At two o'clock P.M. her husband left her perfectly well, and she was observed soon afterwards by the neighbours walking in the yard, apparently quite cheerful. She then went up stairs with the intention of making the bed, and, after shaking it, finding herself unable to proceed, came down stairs, looking exceedingly pale, and on seating herself in a chair, directed her little girl to tell one of the neighbours that she was poorly. They both returned immediately to her assistance, but on their arrival found she had expired. The case thus became the subject of juridical investigation.

On the clothes being removed, the covering next her person was found stained with wet florid blood and watery discharge. After a careful inspection by very competent individuals, the head and body were found perfectly healthy in all their parts. The stomach was distended with undigested food. The uterus was very minutely examined: it measured six inches in length, four and a quarter in breadth, and two in depth. An incision being made the whole length of its anterior surface, the decidua was seen beautifully developed, terminating abruptly just above the commencement of the cervix. On dividing it, the uterine cavity was fully exposed. The placenta appeared in course of formation on the posterior surface of the fundus. The embryo contained within the membranes was unnaturally forced to the summit of the organ by a large and firm clot of blood, which partially concealed the ovum, and occupied two-thirds of the cavity from the fundus to the neck. This coagulum was outside the chorion, but everywhere enclosed by the decidua. It measured three inches and a quarter in length, and one and a quarter in depth. The smooth part of the chorion was very distinctly lacerated in its centre, and around the edges of the laceration was detached from the amnion for some extent by an extravasation of blood. The effusion could only have proceeded from the vessels connecting the amnios with the chorion, every other part of the ovum being perfectly natural. The os internum was nearly closed by mucus, and the effusion was walled in at the cervix by the deciduous membrane, excepting a small aperture in its centre, through which the fluid blood seen on the linen had escaped.

Observations.—Hæmorrhages from the uterus, at an early period of utero-gestation, occasioned by the detachment of the external coverings of the ovum, and the subsequent exposure of the uterine vessels, very rarely prove fatal. A fatal effusion, proceeding from the membranes only, has scarcely been supposed. Very minute vessels may undoubtedly yield a copious effusion*. But to what is this woman's sudden dissolution attributable? In the absence of all unnatural appearances elsewhere, how far is it referable to the uterine effusion and its attendant circumstances? Neither the amount of blood nor its mode of escape (assuming the effusion to have occurred very suddenly) can be regarded as a perfectly satisfactory explanation. It is true, that an injury of a very trifling kind—a blow on the stomach, for instance—has been known to prove suddenly fatal. Lacerations, also, of a trifling extent, have rapidly terminated in death, under the collapse consequent upon the injury. In a laceration which was situated at the cervix uteri, and detected soon after delivery, I found barely 3j. of blood effused in the abdomen;—death arose from collapse. But here we find no injury done to the mother's system;—merely a clot of blood præternaturally distending the uterus, and confining the greater part of the ovum to the superior part of the cavity. Allowing for the great sympathy subsisting between the uterus and

* In proof of this, I may allude to the case of a girl, who died recently in this town under excessive menstruation. But, in this instance, there was a remarkable idiosyncrasy, or hæmorrhagic tendency; a slight scratch invariably occasioned violent bleeding; and whenever the bowels were confined during the period of menstruation, the discharge was always excessive. She died under a menstrual effusion, attended with constipation, and not a vestige of disease was found, excepting a slight ovarian enlargement. Unfortunately, the plug was not resorted to. To the ovarian enlargement the excessive effusion was, I conceive, in a great measure attributable. Uterine flooding, according to M. Lisfranc, is almost constantly connected with uterine disease; but, in this particular instance, the effusion was menstruation in excess, and not flooding, properly so called, with coagulation of the blood.

the system generally during the embryo-formative process, still, to account for so fatal an impression, we must necessarily pre-suppose a habit peculiarly feeble, and the nervous system susceptible of impressions from causes totally inadequate to affect an unimpaired constitution. M. Deneux is the only author who is known to me as having described hemorrhages of this character, a circumstance I was not aware of when I published my treatise on Uterine Hæmorrhage. In his paper on the subject, M. Deneux comprises "any accumulation, extravasation, or infiltration of the blood into some part of the organs of generation, or of the envelopes of the fœtus *." Cases are then described of sanguineous effusion between the placenta and uterus; between the uterus placenta and the external membrane of the ovum (the decidua, I presume, is here alluded to); between the epichorion and the chorion (an effusion peculiar to the first two months); between the amnion and the umbilical vessels; and lastly, cases are given of several kinds of effusion co-existing in the same patient. It will be seen, by this reference, that M. Deneux does not describe a distinct laceration of the chorion together with its detachment from the amnion, and the consequent escape and extravasation of blood within the external membrane; nor do I find any case exactly parallel, either in Dr. Granville's "Graphic Illustrations of Absorption," or elsewhere.

I have recorded this case, not on account of its singularity and interest only, but under the impression, that by directing general attention to it, a better explanation may be given of its nature than it is in my power to offer. I trust the subject will be noticed by some of the numerous correspondents of the Medical and Surgical Journal.

ON THE FUNGATING VENEREAL ULCER.

BY JOHN HART, M.D.

THE following observations are extracted from the Dublin Journal, and are well worthy of attention.

"This form of disease commences in one or more vesicles, seated on the outer or inner surface of the prepuce, on the cervix, more

rarely on the glans, or corona glandis. In females it mostly occurs in the recess between the labia and nymphæ, on the inner surface of the latter, at the posterior commissure, and sometimes at the verge of the anus. Each vesicle, after a few days, is succeeded by an ulcer, which presents the following characters:—a well defined sharp edge, with an elevated border; when on the prepuce, the surface of the ulcer is generally concave, and covered with a yellow, or greenish yellow coating of tenacious pus; often there is a profuse discharge of pus, more especially if the ulcer be on the inner surface of the prepuce, or at the cervix; the pus, in this case, is mostly cream-coloured, and of uniform consistence. This form of ulcer is not so frequently solitary as the Hunterian chancre, but generally occurs in a crop consisting of two or more.

"There is generally a good deal of pain accompanying this affection. The inguinal glands sometimes become tender and enlarged, but scarcely ever suppurate.

"When this ulcer is neglected or improperly treated, an exuberant granulation sprouts from its surface, which is hard and firm when its seat is the glans, and softer when it occurs on the prepuce. I have seen this excrescence generally larger, softer, and of a paler colour, on the genitals of females than on those of males.

"When the fungus is allowed to continue for any length of time, it acquires a greater degree of hardness, and is more difficult of removal; it often expands, so as that its edge overlaps the skin around the margin of the ulcer.

"I have not known a single instance where this ulcer was followed by secondary symptoms, and I therefore consider it to be a purely local affection. I have had frequent opportunities of ascertaining that it was contagious. Men under my treatment for this affection frequently communicated it to their wives, in whom it invariably exhibited exactly the same appearances as those above described."

This ulcer is not affected by mercury, and is cured with escharotics, nitrate of silver, equal parts of savin and muriate of ammonia, sulphate of copper, or strong acetic; and Dr. Hart does not agree with Dr. Wallace in the opinion that mercury is necessary in this form of disease,

ON CLINICAL MEDICINE.

BY C. J. ALDIS, A.B., M.B.

THEY who have given themselves up entirely to the systems, with which medical writings abound, to the neglect of clinical instruction and observation, will find that they have deviated from the right path. A fervent imagination is apt to be captivated by some particular system, but the strong evidence of facts will ultimately eradicate any false hypothesis, which the mind has imbibed. Though ingenious systems may excite admiration, still they are of little importance in medical practice. Many writers, whose superiority consisted in accurately describing the phenomena of disease, and determining the effects of remedies, prove that the extensive science of medicine cannot be confined by a systematic boundary. Such writers inculcate the necessity of observation, and defend us from obscure hypotheses. In them observation and reason are united, the one is not alloyed by preconceived opinions, the other is modified by an attention to facts. Although many systematic writers are remembered with the greatest respect, it does not appear to be on account of the numerous hypotheses which they have constructed, but for the observations intermingled with them. It is not our wish to maintain that hypotheses have thrown no light on the phenomena of disease; many have contributed to the elucidation of disease, and we should collect from each whatever good is to be derived. There are, also, frequently discussed theories with which it is necessary to be acquainted. After such considerations, the following question naturally occurs to us; Whence is our knowledge of disease to be obtained? The daily occurrences in any large hospital will easily supply an answer. From the observation and experience of well instructed medical men in the lecture room and at the bed-side. Having determined the source from whence our information is to be obtained, let us inquire into the advantages arising from clinical medicine. We learn our profession by examples. A person entirely ignorant of the practice of physic can here become acquainted with the phenomena of disease. These, certainly, are contained in books; it is not, however, a mere outline of a complaint with which we are to furnish ourselves, but the successive order of

the symptoms, paying regard to the causes, and to the effects of remedies, which can only be acquired by observation, or, in the words of Rostan, "to know a malady we must see it, observe it, follow it up with attention in the different periods during life, and the traces after death *." At the same time he appreciates the exact description of authors, but remarks on the great difference between the man, who says he has seen a disease, and the man who has read of it. The first is the man of the cabinet, who knows the earth only by esteemed writings, the second is the voyager, who has traversed all countries; the one is doubtful, the other is certain; the reader is obliged to believe, the voyager can judge of the description. This branch, therefore, is to be learnt by making constant observations on the appearance of diseases. In the next place, it will be necessary to ascertain the doses, the method of exhibiting remedies, and the effects produced by them. Diagnosis also will demand our attention. We shall be induced to collect facts, to deduce profitable results, and to observe nature without prejudice. There is also another important subject for consideration, that the symptoms, which usually accompany disease, are occasionally absent, or, in other words, disease is not always portrayed by symptoms. In the writings of Bichat, though not on clinical medicine, we find a zealous disposition for observation, every part of his work teems with facts applicable to the science of medicine, but in his own words, "we are still far distant from those days when the science will be nothing but a succession of facts strictly deduced from each other †." Clinical observations will correct errors, will teach us to observe diseases attentively, and to cultivate with advantage the soil which has been worked upon by our predecessors. In this department nature will form an instructive book.

Old Burlington-street,

LIGATURE OF THE COMMON ILIAC
ARTERY OF THE RIGHT SIDE.

THE lady, a private patient, 45 years of age, the mother of three children, after suffering

* Cours de Médecine Clinique.

† General Anatomy.

pain in the right hip and leg, which she considered rheumatic, for several months, struck the right buttock against the corner of the table, and soon after observed a swelling, which, at the end of 16 months, became so large as to prevent her lying on her side or back, or walking, and gave her pain. It was evidently a gluteal aneurism of great size, although the pulsation was very indistinct. On the 24th August, at the consultation with Sir A. Cooper, Mr. Thomas, and Mr. Keate, the operation of tying the common iliac was performed in their presence.

The lady left town Saturday 21st December, being in good health and spirits at the time.

Mr. Guthrie means to publish the particulars.

LEECHING IN NEPHRALGIA.

BY ROBERT EMINSON, M.R.C.S., S.A.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I beg to transmit you two cases of nephralgia, in which the application of leeches gave instant relief, and after potent doses of opium had failed in even mitigating the excruciating sufferings of the patients.

I am aware that opium is regarded as the chief remedy in such cases, and that general and local bleedings are considered as but secondary constituents in the treatment of apyrexious nephralgia. But from its frequent and complete failure, and the instantaneous relief which has invariably followed topical bleedings, either by cupping or leeches, have induced me in my practice to reverse this plan of treatment, and to look upon the application of leeches to the lumbar region as a point of the first importance and necessity. The speedy easement from acute suffering which they afford is striking, as instances of which the two cases here subjoined may be adduced.

—, æt. 50, was in July, 1833, suddenly attacked with excessively acute pain, commencing in the right lumbar region, and extending from thence half way across to the umbilicus, and once or twice darting to the testicle of the same side, which was slightly retracted. There was nausea, and the urine deeply imbued with blood. Complete apyrexia. Two grains of the extract and one drachm of the tincture of opium were adminis-

tered in a short space of time, but with no other effects than disturbing the head and constipating the bowels. I now ordered a dozen leeches to be applied *parti dolenti*, and the moment they commenced biting, the patient was completely relieved; the pain returned, however, the next day, and the leeches were again applied with the same result, only the relief was permanent.

Another individual, about the same age, and of an uric acid diathesis, was similarly seized with agonising pain in the left lumbar region, darting across the abdomen, and attended with partial suppression of urine, but no feverish symptoms. Opium was in this case also freely administered, but with very inconsiderable relief, and I therefore applied fifteen leeches to the part from whence the pain proceeded, which was about a couple of inches left of the last dorsal vertebræ, with the effect of a complete and permanent cure. The next day this patient voided per urethram an uric acid calculus, equalling in dimensions a full-sized wheat corn.

Lincolnshire.*

REMUNERATION OF PHYSICIANS IN IRELAND.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Now that there is a prospect of a speedy reform in all the branches of the medical profession, may I beg (through the medium of your valuable and widely circulating Journal) to call the attention of the physicians of this country, to one of the many grievances under which they labour. The apothecary can legally recover a remuneration for his attendance, the surgeon can recover, but the physician, who has expended a great deal of time and money in acquiring a knowledge of his profession, and who pays a large tax to the government, (for the stamp on which a medical degree is granted costs ten pounds,) cannot legally recover his fee. I have had an attendance on the son of a rich farmer for 18 days, whilst labouring under a severe case of acute rheumatism; after my attendance he offered me the large fee of two pounds for thirty-six visits.

Now, Gentlemen, I am sure that you and the medical profession will agree with me,

that we ought to have some legal protection for the recovery of our fees.

I have the honour, Gentlemen,
to remain your faithful servant,
AN M. D.

Boyle, Jan. 3rd, 1834.

DR. JOHNSON AND THE MEDICAL
GAZETTE.

*To the Editors of the London Medical and
Surgical Journal.*

GENTLEMEN,—In the last number of the Medical Gazette there is a heading in the table of Contents, which stands thus:—"Combination against the Medical Gazette;" and in the body of the leading article I am made to say, in the Westminster Medical Society, that I "had entered into an arrangement with the *Lancet*," evidently with the view of supporting the charge of "combination." The Editor goes on to state, that "in the account which has been published of this, a good deal of dressing has been had recourse to, and the distinct avowal that overtures had been made and rejected is glossed over." I appeal to more than one hundred witnesses in the Westminster Medical Society, including yourselves, whether I ever uttered a syllable about entering into an arrangement with the *Lancet*. The whole is a gross fabrication, and contains not one word of truth. The allegation contained in the above statement is as false as the statement itself. I have entered into no combination of the kind, or of any kind, with the *Lancet*, or with any other Journal. My time, I hope, is better occupied than in forming leagues, coalitions, or cabals against the Medical Gazette. The statement which I made in the Westminster Medical Society is correctly given, and not *dressed*, in the different Journals; and I am astonished that an Editor of a public Journal should condescend to employ such a palpable misrepresentation, with the hope of injuring a contemporary journalist, and making it appear that a combination was formed against himself. I am sorry that, in his laborious researches through the volumes of the Medico-Chirurgical Review, he has selected matters so little useful to his readers. If all the charges of inconsistencies were brought home to my door, they would not amount to any crime, and they are shared by

me with many men of greater note than even the Editor of the Medical Gazette himself.

I am, Gentlemen,
Your most obedient servant,
JAMES JOHNSON.

January 7th, 1834.

P.S.—As I never yet have done or said any thing which I am afraid or ashamed to avow, so I have no hesitation in acknowledging that I may have been mistaken as to Dr. Dill. It is well known, that about the period in question I suffered a severe and protracted illness, during which I was often absent from town, and unable even to correct the proofs. I am yet ignorant of the names of many contributors at that period. The Editor of the Gazette lays great stress on the style, and makes a quotation, which he thinks I cannot parry, as Dr. Dill was dead at the time. It is at page 536, beginning thus—"Turn which way we may," &c. This quotation, if written by me, would certainly prove me inconsistent; but the Gazette had not been published twenty-four hours before the author of the paper came to me, and offered to communicate his name to the Editor of the Gazette. This he will do in the course of the week. He is well known to my contemporary, who will not doubt his authority.—J. J.

Review.

A Lecture Introductory to a Course of Lectures on Anatomy, Physiology, and Surgery, delivered at the School of Medicine and Surgery, Gerrard-street, Soho. By G. D. DERMOTT, Lecturer on Anatomy, Physiology, and Surgery. 8vo. pp. 24. London: 1833. Fellowes.

THIS lecture has attracted our attention in consequence of the mysterious subjects which the author has endeavoured to elucidate, and also on account of his views on the polity of the medical profession in this country. He divides his subject into two parts.

"Part I.—(Physiology), treats of the varieties of structure—the properties of Vital Principle—the materiality of the Mind, and its compatibility with the Doctrine of the Christian Religion.

"Part II.—(Medical Politics), contains Observations on the real state of the Profession—Aldersgate-street Dispensary—cause of the

evils, the threshold despotism of Money, influence of hereditary Aristocracy, and private interest contaminating our National Institutions and Charities, and oppressing Talent and Industry—the Remedy, and the good effects which would be produced by it—The Anatomy Bill—its deficiencies—its Abuse and the evils that have been produced thereby—the requisite Amendments.”

After having given his views on the various tissues, he next considers the vital principle, a subject that has eluded the grasp of the ablest physiologists of ancient and modern times. We shall allow the lecturer to detail his opinions.

“The blood is the grand circulating magazine of vitality for the purpose of supplying all parts of the body with life—all the phenomena of life conspire to prove this:—increase the circulation (to the acmé compatible with health) and you increase animal power—diminish it and you diminish animal power—abstract the whole of the blood and you destroy life.”—p. 7.

“The vital principle I believe to be an invisible material substance existing in the blood, and by its peculiar stimulus, stimulating the arteries into action, and thus life, as it were, develops itself, which action of the arteries may be a means of secreting it or throwing it out of the blood, whereby it becomes developed by its effects or properties in different structures; besides this principle being separated from the blood by the living agency of the extremities of arteries, I believe that this principle, like heat, permeates through living structure, and is communicable from one living substance to another. This must be the case, or the coats of the minutest vasa vasorum could not possess vitality; but the substance to receive vitality must be in a state of predisposition to do so, and must I think be in contact with the substance from which it is to receive it.

“For instance coagulable lymph, separated from the blood and no longer in contact with the living surface which produces it, or with any other living surface, coagulates—and this coagulation is an action of life, but is the *dying* action of the lymph. On the contrary, keep this coagulable lymph in contact with the living surface, and it not only coagulates, but continues to have communicated to it a supply of vitality from the producing surface—

veesels are created in the coagulum, by the act of vitality within it—then this coagulum beginning to have a vehicle of vitality of its own—such an affinity of life is created between the two, as to produce an union of vascularity between the coagulum and the contiguous surface of the membrane. This affinity and communication of life is well seen between two contiguous cut surfaces, producing an union of vascularity—for there must be a reciprocity,—an unity of action,—to produce an unity of substance.

“It is this affinity of life between two living parts which occasions the sympathy of contiguity described by John Hunter.

“As the blood or the vital principle circulates into the various structures, it is of course distinguished by other properties than the general one of exciting organic action throughout the frame, these properties are those living properties distinguishing these various structures, functionally, as living structures, for instance, the vital principle in muscular fibre is known by the contractibility of muscular fibre, in the nerves it is displayed by the properties of sensibility in some, volition in others, and respiratory action in others, the vital principle circulating into the base of the brain, is developed by the same properties of animal vitality as in the nerves; and this part is probably the seat of the various animal propensities excited into action by the various sensations created in parts, and with which it is continuous through the medium of the nerves. But the vital principle ascending into the superior part of the cerebrum, so abundant in man, is there developed by the higher range of vital powers, namely, perception, (the action of the nervous sensibility of the brain) thought, memory, and volition, by the just exercise of which man reaches to God and Heaven, as well as attains all necessary earthly knowledge.”—pp. 9, 10.

We shall comment on our author's doctrine of the materiality of the mind in our next.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, January 4th, 1834.

DR. GREGORY in the Chair.

THE minutes of the last meeting having been read and confirmed, Mr. King rose for the

purpose of laying before the Society one or two points connected with the scarlet fever, which had so lately raged in this metropolis; he alluded to the great debility which attended upon the complaint, and the swollen state of the tonsils, in which none of the usual anti-phlogistic means were found of avail; the condition of the patient thus became very distressing, for in consequence of this tumefied state of the glands, it was impossible to close the mouth; in some of these cases delirium was produced, and great difficulty of breathing, proceeding even to suffocation. He had found that free incision with a long pointed bistoury, carried from before backwards completely through the amygdala, afforded great and immediate relief; and still farther good ensued from the use of gargles of hot water, which caused the blood to flow freely from the divided parts.

Mr. Hunt thought Mr. King's communication one of great importance; with regard to the treatment of the debility in this disease, great variation had taken place within the last twenty years; for in former times brandy, and other means which tended rather to increase than to check this symptom, were used, but now he was happy to say that the treatment employed was very different, and much more successful. He wished to know whether the glands were at all enlarged previous to the disease, and whether in the cases in which incisions had been practised, the ulcerative process had been averted or not.

Mr. King said the glands were slightly enlarged, but that after the use of the bistoury, they gradually became absorbed.

Mr. Preston had attended several cases in which the swelling had occurred, whilst the other symptoms were slight. He had noticed in this disease a peculiar degree of tenderness in the lumbar region, an excited state of the pulse, and a dry state of the skin. The remedies which had proved most beneficial, were purgatives, inducing a great secretion of water, and sometimes even bleeding to a considerable extent; in one case he had taken blood from the jugular vein with decided benefit.

Mr. Greenwood and Mr. Hunt made some farther remarks upon the complaint, after which the meeting proceeded to discuss the motion proposed by Dr. Epps at the last meeting.

The resolution having been read, Dr. Epps

said that this matter had occasioned considerable discussion in the public prints; he had not communicated with any one upon the subject, nor was it through any party feeling that this motion had been brought forward. After three nights of discussion, all the resolutions up to the 8th had been passed, when Dr. Gregory, a gentleman they were all glad to see in the chair, came forward, and proposed an amendment to this resolution, and the most extraordinary part of the affair was, that the ballot on the amendment was demanded for the succeeding evening. No chairman had a right, in his opinion, to postpone a ballot upon a question to a following day, when there was abundant time for it to take place on the same evening. This practice of the chairman taking upon himself the question of delaying the ballot, had lodged the Society in an absurdity. Dr. Gregory himself had moved the 9th resolution, although the 8th was banished the meeting; if the Society had not proceeded to the 9th resolution until the 8th had been settled, it would have borne some show of consistency; but as the proceedings had been so strange, he thought himself bound to take the sense of the Society upon the question.

Mr. Hunt, after seconding Dr. Epps's motion, said he felt sure that one word of explanation from Dr. Gregory, the first father of medical reform, would set the matter right, and he trusted that this gentleman would not hesitate to afford to the meeting such explanation.

Dr. Ferguson expressed his regret at the want of unanimity of the Society on this subject. The question, in his opinion, resolved itself into a very simple form, merely whether there was a by-law existing or not on this question; he believed that no by-law did exist, and if not, it became necessary to look for a precedent.

Mr. Burnett said that the onus had been moved from their own shoulders on to his, he had therefore to refer to the meeting of the 7th. He thought the members were greatly in favour of the 8th resolution; there certainly were voices calling out for the ballot, amongst which he had heard that of Dr. Gregory; he had, however, considered these expressions merely as ebullitions of feeling, and that the ballot was an appeal from the president; he thought that it was very irregular for a member

to come forward on a succeeding evening, for the purpose of doing away with the proceedings of that night.

Mr. Hunt, Dr. Copland, Dr. Johnson, Mr. Chinnock, and one or two other gentlemen, joined in the discussion, after which an objection, raised by Mr. Chinnock, as to the time for balloting, having been overruled, the vote by ballot upon the question was taken, the numbers were, for Dr. Epps's motion 45, against it 18.

Dr. Epps then proposed the following resolution.

"That the proceedings of the meeting of the 14th, so far as refers to the ballot taken upon the amendment of the 8th resolution, and upon the original 8th resolution, be rescinded."

Upon a show of hands, there appeared to be a large majority in favour of the motion. Notice was then given, that on the succeeding Saturday Mr. Johnson would give some observations on venereal sores, after which the meeting separated.

THE

London Medical & Surgical Journal
Saturday, January 11, 1834.

MEDICAL REFORM.

OUR readers will find in another part of this Number, a full report of the proceedings at the Westminster Medical Society, on Saturday last, upon Dr. Epps's motion, to review the course which the Society was led to adopt upon Dr. Gregory's celebrated amendment. The ballot upon the amendment, which it will be recollected, took place the evening *subsequent* to the discussion, was declared irregular; and, as the irregular proceedings have been erased from the minutes, the eighth resolution, in favour of the One Faculty to preside over the whole profession in the United Kingdom, stands as the recorded sense of the Society. But if resolutions, like oaths, are to be taken in the sense of the proposer, it is evident, from the observations we made in our last Number, that it was very far from

the thoughts of Dr. Johnson, the mover, and of the Society, to vote for the total annihilation of the existing corporations by means of the establishment of this One Faculty. At the same time, it is perfectly evident, that some of the Members of the Society, in voting for the resolution, have assigned to it a construction, which we cannot say is unnatural and forced, but which certainly far exceeds the limits Dr. Johnson has assigned to his scheme of Reform: and it was, by seizing adroitly upon this play of words, that Dr. Gregory was enabled to achieve that egregious piece of duplicity, if report says true, for which we must accord him a sad pre-eminence. It is difficult to give a consistent account of the motives of persons, who place themselves in suspicious positions. Whether Dr. G. *penned* the resolution originally with the thought prepossession of the uses to which this ambiguity might be turned for the moment, or whether the happy idea of making him bastardise the offspring of his brain, was owing to others who worked the puppet, and who, in the pursuit of their object to sow dissension, overcame his respect for his own consistency, we know not; but clear it is, that, as long as the imputation, broadly asserted, of his authorship of the resolution remains uncontradicted, so long will abide a stain upon his reputation for plain dealing. We would willingly discredit the story; but, alas, his silence has left us no room for charity. But, waiving these reflections, and returning to the opinions of one of the large parties, who supported the eighth resolution, we repeat, it cannot be denied, that some zealous members of the profession go far beyond the declared intentions of Dr. Johnson, with respect to the existing medical corporations. A great law-giver, who seemed to have had a sheet of white paper for his reforms, when

he was questioned upon the propriety of some of his new institutions, is said to have answered, that he gave the people such laws as they could bear, and not such as were good in themselves. The plain necessity, that every reform should be practicable, is, however, often overlooked. In estimating what is practicable, great regard must be paid to the prejudices, which are found existing in the bosom of society,—let reason say what she will to the contrary,—names are things with the bulk of mankind. In speculating, therefore, upon the remodelling of our medical institutions, it has occurred to us, to consider by what means we might imitate the gradual progress of our political constitution towards perfection, and at the same time avoid the shock of prejudice. We are not advocates for any sudden exertions of the *formative* effort.

Let us review, for a moment, the medical institutions which are at present in existence, and see whether a few simple changes may not accomplish all the good which can be expected from a total revolution in the republic of medicine—names and all. The capital of each of the three branches of the United Kingdom has its College of Physicians and College of Surgeons. These Colleges were not unsuited to the times when they were established; and there is attached to some, if not to all of them, the prejudice of age. The several Colleges of Physicians have, in general, their exclusive jurisdiction limited to the respective capitals. The surgeons have scarcely any legal rights at all. If, now, the authority of the College of Physicians was extended over the whole kingdom, so that none should practise physic but such as were members of that corporation; and if it were required of every practitioner in physic that he should be a member of the College of Physicians, and *vice versâ*, then, in the first place,

there would of necessity be a uniformity in elementary education amongst all the members of the united professions; and, in the next place, that jealousy which at present divides the physician from the surgeon would cease, when each practitioner was a member of the conjoint corporations. In short, it appears to us, that without aiming at the destruction of either of these bodies in the respective capitals, it is possible, by a due extension of their powers, and by a liberal and searching reform of their governments, to make them the natural and legitimate heads of the conjoint professions of medicine and surgery; which would then have no other separation than as the talents of individuals might lead them ultimately, in the course of their professional career, to devote themselves more exclusively to the one branch or the other. It may be said, that this, after all, is but three faculties under another name. So far as it proceeds upon identifying the now distinct education of physicians and surgeons, we admit the similitude: but so far as it respects the already existing corporations of physic and surgery, and seeks to unite their interests and extend their influence, we see a broad and intelligible diversity.

All bodies, other than these several corporations, should be treated as mere schools of medicine, whose character should depend upon the education with which they furnished their students. In this country, the apothecary and the surgeon now join trades; the University of Edinburgh is labouring hard to open the market to her doctors; we desire the union of the surgeon and physician; and, as to the trade, that shall be the apothecaries' exclusive care. But any change must respect the vested rights of individuals. We shall return to the subject in our next.

DR. JOHNSON AND THE MEDICAL
GAZETTE.

In a preceding page will be found Dr. Johnson's rejoinder to our contemporary, of the Medical Gazette, which exposes the real motives of that consistent character. In an article of nearly ten pages, he endeavours to show the inconsistencies of our valued and respected contemporary, the Medico-Chirurgical Review; and ascribes every article, that appears in that work, to Dr. Johnson, as Editor, though he well knows that many writers contribute to that Review. He argues, that Dr. Johnson, as Editor, is personally responsible for every thing which appears in his journal. It would be as reasonable to hold the Editors of the Times or Herald personally accountable for every thing inserted in the papers which they conduct. How often does it happen, that we read opinions and doctrines in Medical Journals, to which the Editors do not subscribe, and on which they would not act in treating their patients; but, according to Macleod's logic, the Editors must adopt every thing. Ridiculous as is the charge against a staunch reformer, who has consistently advocated the suppression of medical abuses for the last twenty years, and has earned the fame of the hatred of the College of Physicians for his manly conduct in the cause, our contemporary has not hesitated to make it. It was necessary to say something,—and the triumph of circulating the attack for a week, without the danger of contradiction, was great in the eyes of a party, who have nothing on all sides but defeat to expect. In making these observations, we beg to state, that we have not spoken a single word to Dr. Johnson about Reform. As to our having entered into a combination against such a thing as

the Gazette, it is false and preposterous. Gentle readers! only think of "Wakley, Johnson, and Ryan" combining against Macleod. The idea has not only excited our contempt but also our risible faculties to such a degree, as to endanger the safety of our sides. This imbecile reminds us of the frog and the ox in the fable; he assumes an air of importance which the profession will treat with scorn. Seeing reform is certain, he is almost mad, that his bowing and scraping to the magnates of the College of Physicians are at an end, that his longing after a Fellowship is not likely to be gratified, and that his patrons must put their tottering house in order; for a reformed Parliament is not to be cajoled by monopolists, who neglected to use the power conferred upon them for the benefit of society and the profession at large. We have been repeatedly asked the reason why we oppose a College to which we belong; and our answer invariably was, because, in its present state, it is an impediment to the advancement of medical science, it is tyrannical, unjust to its members, and it is no protection to the public health. It has also been remarked, that we pledged our honour to support its interests; and so we did, so far as these are based on equity and justice, and are conducive to the advancement of science. But we refused to promise our support to some of its laws, which were concealed from us, and which we sincerely believe to be corrupt.

Nevertheless, we do not wish to see it destroyed, but reformed, and suited to the age in which we live. We publicly declared at the Westminster Medical Society, in the presence of at least two hundred members of the profession, that we were not levellers; and yet our voracious contemporary designates us such.

CLOTS OF BLOOD IN THE HEART, ORGANISED OR TRANSVERSED BY NUMEROUS VESSELS COMING FROM THE SURFACE OF THE VENTRICLES AND AURICLES, AND INJECTED FROM THE BRONCHIAL ARTERIES.

BY ALEXANDER THOMSON, M.B.

ON the 5th of October, 1833, I found the body of a woman, in which there were general and recent adhesions of the greater portion of the abdominal to the intestinal peritoneum, both of the intestines and of the other abdominal viscera, as well as universal adhesions of the costal, pericardial, mediastinal, and diaphragmatic pleurae, with the pulmonary pleura. There were other morbid appearances, of which no note was taken; but the upper lobe of both lungs was in the yellow granular stage of hepatisation, and the parenchyme of the remainder of the lungs was in the first stage of inflammation. In either lung there was in the upper edge a cavity of at least three-fourth of an inch in diameter, of an irregular rounded form, having a distinct lining membrane, from which proceeded several irregular pedicles, varying in form, length, and thickness, and supporting, free from the sides, except by these pedicular continuations, a mingled mass of condensed cellular tissue, and matter of a condensed, hard, gritty, greyish, and yellowish-white appearance, resembling a bony deposit. Between these masses and the walls of the cysts, there was a greasy greyish-white mass, resembling muscular substance that has been long standing under water, or buried in moist earth, but no liquid whatever. As far as could be traced, there was no direct communication of these cysts with the bronchial tubes or with the pulmonary parenchyme. The centre of this substance in the right side was one solid mass, resembling the dense bone of an old and compact cranium. I injected the bronchial arteries carefully with size, coloured with vermilion, and then, after leaving the parts for a sufficient length of time for the size to set, washed the piece well with cold water, and proceeded to the examination. During the injection, the fluid returned into the aorta through the orifices of the œsophageal arteries in considerable quantity, thus proving the anastomoses of the bronchial with the œsophageal arteries. The injection was found

to have penetrated the muscular and cellular coat of the œsophagus, and to have minutely injected in a stellular manner the cellular tissue subjacent to the mucous in the whole length of that tube, from a level with the upper edge of the sternum to the radiating termination at the cardiac orifice of the stomach, and in the membrane of the stomach for three or four inches' distance, all round the cardiac orifice, to have universally injected the sub-mucous cellular tissue of that part of the trachea below the level of the upper edge of the sternum, and of all its traceable branches, yet in this case without producing any effusion into these tubes. It is worthy of remark, that the injection was far less traceable in the more solid than in the recently inflamed parts of the lungs, but was not, as in the tuberculous lung injected with Mr. Fisher, to be found not only not more defined, but not at all in the walls of the cysts of the bony substances. Yet in the centre of one of these masses there was a roundish cavity, filled with pulpy, translucent, yellowish-grey matter, in which there was a fine mesh of vessels filled with the vermilion injection, proceeding from a point in one of the pedicles, yet the vessel traversing the pedicle could not be traced. For the injection, however, to have reached the pulpy central mass, surrounded with the bony concretion, without having been effused into the cavity or being traceable in its enveloping cyst, it must have traversed one of the pedicles, and that by a vascular entrance, thus proving these masses to be at least in part organised. The injection was traced into all the bronchial glands, the cellular tissue of the mediastina universally, the greater part of the adhesive bands, uniting the two pleuræ, and passing from them into the costal pleura. And here I may be allowed to reason as follows: these adhesive bands when organised are admitted to resemble in all their characters cellular tissue, and therefore to be serous, yet, as they contain vessels, and these vessels of new formation, yet conducting themselves in their anastomoses and inosculation as vessels belonging to other serous membranes, and as they contain no subjacent cellular wall between their laminae, they give an instance of the serous membrane being capable of receiving blood, and thus controvert the notion that injection of the vessels in serous inflammation is in the subjacent serous cellular tissue, and not in the serous membrane itself. I have no

doubt of this fact from actual dissection of the pleura, and from a preparation preserved in my museum; but it is useful to point out any accessory proofs of this fact as drawn from analogical deduction. The injection was also traced into the coats of all the great thoracic vessels, of the aorta, ascending and descending vena cava, pulmonary artery, and veins, into the substance of the heart, of all its valves, and into the serous linings, though in these much more profusely in the lining membrane of the pulmonary auricle and ventricle, than in the remainder. In the descending thoracic aorta even, several patches of ramified injected vessels were met with, in patches of the size of a linseed in the lining membrane, and removed with that membrane. A few, also, were found in the same membrane of the pulmonary artery, and numerous ramifications in both the second and third coats of these two arteries. Numerous ramifications were also found in the whole of the fibrous parts, and in the upper portion of the serous part of both the capsular and cardinal portion of the pericardium. But the most important and interesting facts are still to come. All the branches, both great and small, of the pulmonary arteries and veins that could be traced, contained injection mingled with the semi-fluid blood, thus clearly proving the numerous anastomoses of both with the bronchial arteries. But still more, the semi-fluid blood in all the cavities of the heart was mingled with the same, although none of the injected vessels on the inner surfaces of those cavities could be traced to have been ruptured; thus proving the great extent of the anastomotic communications already deduced of all the vessels of the lungs with the bronchial arteries. Previously to the injection, in opening the aorta to find the orifice of the bronchial arteries, I withdrew numerous solid, indurated, yellowish white clots, elastic, dense, moulded into the form of the arch of the aorta, of its valves, of the innominate, carotid, and subclavian arteries, and of which a portion remained in the systemic ventricle. This mass had all the appearance of boiled ligamentum nuchæ, and was of a yellowish white hue, and opaque; a similar mass in every respect was found in the pulmonary ventricle and artery, and its branches terminating in them gradually, in a softer clot of a black colour, yet adherent, and mingled with white, opaque, long masses; similar masses were also found in both the auricles.

These masses being in all the cavities surrounded with a black semi-fluid, mingled with softer and translucent greyish-white and yellowish white clots, were interlaced with the columnæ caruæ, and adhered very strongly to them. In all the hard masses of dense white clot, thus adherent after the coloured part of the blood had been carefully washed away in a pailful of clean water, and with somewhat rough handling, we were surprised to find numerous branching, slender, longitudinal vessels, dividing, anastomosing, and inosculating in their proceeding, and traceable all over their surfaces, particularly presenting orifices when the clots were cut across, these vessels being much more numerous in the softer parts of these masses than in the more indurated ones, and gradually diminishing in number towards the more solid and indurated parts. Those parts of the clots in the pulmonary ventricle and auricle were more injected than the others, and had more numerous vessels connecting them to the walls of the ventricle.

Such are the important facts resulting from this experiment, from which the following consequences may be drawn:—

Numerous anastomoses between the bronchial and the pulmonary artery and vein, and also the œsophageal arteries.

Injections of the mediastinæ, of the costal, pulmonary, and pericardial pleuræ, of the substance of the heart, of all the walls of the great thoracic vessels, of the fibrous part of the pericardium, of the bronchial glands, of the adhesive bands of the pleuræ, of the centre of the ossific deposits in the lungs through the bronchial arteries.

Organisation of clots in every cavity of the heart, in various stages, and consequent formation of these clots some time previously to death, without any trace of inflammation or ulceration of the surfaces of these cavities.

Organisation of the ossific deposits in the lungs, as proved by their injection.

Injection of the serous membranes themselves, as proved by the injection of the adhesive bands, of the lining membrane of the heart, aorta, and pulmonary artery and vein.

These facts regarding the heart and its lining membrane and substance, and also those regarding the injection of the clots, were moreover seen and verified by Dr. Ricord, at the Hôpital des Vénériens; by M. Marrote, his interne; and by M. Rattier, his pro-

sector; by MM. Louis, Boyer, and Velpeau, medical men of La Pitié; by MM. F. Pelletier, Isidore Boudin, Ph. Gachet, Dupré, and Viget, and several others, internes of La Pitié; by Messrs. H. Bowditch, T. Stewardson, O. W. Holmes, English medical pupils; by Mr. John Stanton and Mr. Charles Linton, surgeons of London; by Dr. Rogers, Dr. Armstrong, and Mr. Wilkinson, surgeon; and by M. Berjat, who is preparing a work on the diseases of the arteries, and in whose museum the preparation is to be preserved.

The whole of the facts were seen and carefully examined by Messrs. N. Welsh, R. C. Bateinan, James Sheehan, and Thomas Keene, and several other medical pupils.

French Medicine.

New Method of treating Circocoele, by M. Breschet.

SINCE the extirpation of the spermatic and scrotal veins, whose varicose dilatations constitutes circocoele, has been tried without success; nearly all modern surgeons have regarded this complaint as incurable; they therefore have contented themselves with prescribing palliative remedies. M. Breschet has, however, effected a cure in two instances, at the Hôtel Dieu, by using pressure with a small pair of forceps, something like those invented by Assalini for aneurism. The vein is separated from the other component parts of the cord, and the forceps are applied to it, the pressure being gradually increased by means of a screw, which retains the two plates of the instrument in contact. The question has been asked,—Whether it be possible to compress between the instrument the spermatic vein, without also exposing to pressure the other parts of the cord? Upon this subject Bichat has remarked, that in the healthy state it is easy to separate the spermatic vein from the cord; and that in the dilated state of the veins in this complaint, it becomes still more simple. In the operation practised by M. Breschet, only the principal trunks are obliterated, so that the circulation, after the cure, is still carried on with facility.

Arsenic, and its Properties.

M. Carles and M. Bielt have shown, that the most common physiological effects of arsenic are an increase of heat throughout the

whole body, a slight burning sensation in the throat, extending even to the stomach, a very remarkable increase of appetite, great thirst and diarrhoea, an augmentation of the secretion of urine, of the perspiration, and of the saliva; although diarrhoea is generally caused by the use of it, it is not a constant symptom; for sometimes constipation to a great extent takes place. As a therapeutical agent, according to M. Cazenave, arsenic possesses very remarkable virtues; its apyrexial qualities are indisputable, and its resolvent action is very powerful; it constitutes one of the most efficacious means of combating intermittent fevers, and as a remedy in some of the diseases of the skin it is invaluable. In eczema and chronic impetigo it has been found very serviceable, but in the papulous affections it is of less benefit, and in nearly all the different forms of porrigo, acné, and syphilis it totally fails. In elephantiasis existing in scrofulous constitutions, the use of it has been attended with considerable advantage. The preparations preferred by the author are Fowler's solution, that of Pearson, and the one of the arseniate of ammonia.

Structure of the Lymphatic Vessels.

Professor Mojon says that the appearance in the lymphatics, which anatomists have described as valves, are in reality true sphincters; these sphincters are formed by circular fibres, which, diminishing in certain parts the calibre of the lymphatic tube, occasion the appearance of the nodosities which are seen on the surface. These contractions are still more visible when the lymphatics are injected with any liquid; it may also be observed when this system is in a state almost varicose, as in a subject with anasarca. If the two ends of one of these varicose lymphatics be pulled upon the nodosities disappear, and the pretended internal valves are no longer visible. The fibrous membrane, of which Mascagni speaks, appears to the author to consist of longitudinal and oblique fibrils crossing each other, the longitudinal being attached to the transverse bands which constitute the sphincters; thus, the longitudinal fibres, by contracting, draw one sphincter towards the other, whilst the oblique ones diminish the diameter of the tube: by means of this mechanism, the fluid which penetrates into a lymphatic, irritates the portion of the vessel which it fills;

it contracts upon itself, diminishes its cavity, and the fluid is thus propelled along: this peristaltic action is synchronous with that of the intestines, and may be observed in the lymphatics, which traverse the mesentery, by opening the abdomen of an animal two or three hours after a good meal.

Professor Magon says that by admitting this organisation, he can explain the retrograde movement of liquids in the absorbent system, spoken of by Darwin and others, and which is incompatible with the idea of valves.

Novel Mode of Applying Leeches.

Dr. Mojon, of Genoa, recommends the following method of applying leeches. He places them in cupping-glasses, and, having exhausted the air by means of a small lighted match, applies the glass to the part from which he wishes to extract blood; the leeches, thus deprived of air, more quickly fasten upon the distended skin. He considers that this very simple and facile method of applying leeches possesses the following advantages over the common method:—by forming a vacuum the necessity for holding the glass upon the place is done away with; the tense state of the skin, caused by the cupping-glass, not only puts it in a more favourable state for the bite of the leech, but the sensibility being somewhat destroyed, the pain is much diminished, the blood continues to flow into the glass after the leeches have fallen, and thus almost any quantity may be obtained.

French Hospital Reports.

MAISON DE SANTE A CHAILLOT.

Diseased Erectile Tissue.—Tumours of the same nature found in the Brain.

M. FARCY, a bachelor, æt. 25, contracted syphilitic ulcers on the glans penis, blennorrhagia, and pustules; the usual remedies overcame these symptoms, but about twelve months afterwards he began to feel trifling pains in the right testicle, which became slightly enlarged; many different plans of treatment were resorted to, but in vain, as the tumour gradually increased in volume. At the end of four years, Professor Majolin recommended the removal of the diseased growth, as the patient's health had become much disordered from the pain and inconvenience, oc-

casioned by the enormous distension of the scrotum. On the 19th of July he underwent the operation, from which he rapidly recovered. The tumour was of an oval form, ten inches in its greatest diameter, eight in the smaller one; it was of a spongy areolar substance, divided in many places by septa, and enclosed in a fibrous cyst, from one to three lines in thickness; a large quantity of blood escaped from it, which, however, did not appear to come from any particular vessel, but from the surface in general. Its inferior part was of a hard elastic texture, perforated by numerous canals communicating with one another, and by means of which the blood freely escaped. This portion of the tumour was boiled for a considerable time in distilled water, and exhibited the following appearances:—it became much hardened, and lost three quarters of its weight; the evaporated fluid gave gelatine; that which could not be dissolved, consisted of albumen and coagulated fibrin. The portion contained in the upper part of the cyst was of a softer texture, somewhat resembling a clot of blood in appearance; the right testicle could not be found.

For some months afterwards this gentleman lived very freely and enjoyed good health. On the 1st of October he complained of slight itching in the right arm; this symptom soon disappeared, but on the 5th he was seized, whilst in a café, with numbness and loss of power in his right hand; his arm then became violently agitated with spasmodic contractions, and to these symptoms succeeded a severe epileptic fit. He then entered the Maison de Santé à Chaillot, when he had paralysis of the right hand, cephalalgia, and frequent returns of the epileptic fits. The attacks became more severe, and on the 1st of November he died.

Autopsy.—On opening the cranium twenty-four hours after death, a violet-coloured spot was found in the left hemisphere, near the junction of the posterior with the two anterior thirds of the cerebrum, and immediately beneath the posterior part of the left lateral ventricle; this proved to be the projection of a tumour in the substance of the brain, as large as a horse chesnut; near to it was found another, smaller in size; and between two of the convolutions was situated a third, of the diameter of a hazel nut; two tumours of the same kind were found in the right hemisphere, but more towards the back part of the ven-

tricle; the substance of the brain round them was in a state of rammollisement, the remaining part being, however, perfectly healthy.

These tumours had no cysts, and were very freely supplied with blood; in their interior was found a structure similar to the diseased erectile tissue which existed in the scrotum; a sanguinous spongy substance from two to five lines in thickness surrounded this.

HÔPITAL DE LA CHARITÉ.

Poisoning from Nitric Acid—Death three months afterwards—Autopsy—Scirrhus of the Pylorus, and commencement of the Duodenum, with enormous dilatation of the Stomach.

ALPHONSE LECLERC, *état.* 34, of a melancholy temperament, drank some nitric acid eight days before his admission into the hospital. He had taken a considerable quantity, but immediately afterwards rejected the greatest portion of it. Magnesia was immediately given to him, but for the first two days, he was tormented with vomiting, and complained of ardent thirst, great pain in his throat, with difficulty in swallowing; leeches were applied to the neck and epigastrium, and emollients of all kinds were used. At the time of his admission, eight days after this event, evident traces of the action of the poison existed, the inside of the lips, the uvula, the arch of the palate, and the back part of the throat were entirely covered with ulcerations, and scabs of a greyish colour; the parts thus injured were swollen, painful, and gave a very offensive fœtid odour. From the hoarseness of the voice, and pain in the course of the œsophagus, increased during deglutition, it was supposed that the superior part of the larynx, and œsophagus was the seat of lesions similar to the preceding. The gastric symptoms, such as nausea, vomiting, and pain, had much diminished at this time, the pulse was small, varying 92 to 96, and there was no febrile heat of skin. Leeches were applied, demulcent drinks, and a diet at first low, but afterwards consisting of milk, were prescribed with so much advantage to the patient, that at the end of twenty-one days he left the hospital.

Strict injunctions were given to him respecting his diet, but he did not pay any attention to them, for three weeks after his departure he again presented himself for admission; he

stated that the pains in the region of the œsophagus and stomach had returned, and that he had frequent attacks of nausea and vomiting, accompanied with colic pains, and constipation; he had become very thin; his pulse was frequent and small; tongue pale and dry, and breath very fœtid; there was apparent fluctuation in the abdomen and pain on pressure; he complained much of wind, and all the medicines which were given to him were instantly rejected; he continued to grow worse, and, on the 21st of September, he expired.

On making an examination of the body 36 hours after death, the stomach was found enormously distended; at the fundus the mucous membrane was in many places totally destroyed; the pyloric end was of a deep red colour, and about this part there were the remains of two large ulcerations in which the cicatrization had already far advanced. The pyloric orifice was so small that a small sound was with difficulty passed through it; the walls of the stomach in its neighbourhood, and the duodenum for an inch and a half, were very much thickened and indurated; the valve itself was from four to five lines in thickness, and on being cut into, exhibited all the symptoms of confirmed scirrhus; the rest of the alimentary canal did not present any appearance of disease, nor was there found any fluid in the abdominal cavity; in the œsophagus traces of ulceration, similar to those in the stomach, existed.

Tumour weighing four pounds a half situated in the Neck—Exstirpation.

PIERARD, *état.* 47, was admitted into the hospital for an enormous tumour, situated on the left side of the neck. About six years ago, he perceived a slight enlargement, which was perfectly moveable; for four years this did not increase, but since that time it has acquired the size of a man's head. It extends from the sternal portion of the clavicle upwards to the lobe of the ear, and backwards to within an inch and a half of the cervical spinous processes; it is hard, lobulated, and moveable, and shaped like a pear, its base lying on the clavicle. As the man's health was not much deranged M. Roux on the 3rd of August proceeded to operate. He made two semi-elliptical incisions over the tumour, and then having carefully dissected to the base,

commenced separating it from the attachments; it did not adhere very closely to the fasciæ of the neck, nor was it connected with the thyroid gland, or larynx; it was, however, loosely attached to the common carotid artery and internal jugular vein, by cellular tissue; but between it and the external carotid, the union was so intimate that it became necessary to use the bistoury. Several arteries were tied, and the operator was compelled to place two ligatures on the external jugular vein, which was then cut between them; in the course of the operation the superior laryngeal nerve, and one or two branches of the hypoglossal, were divided, a slight spasmodic action of the larynx was then perceived, but this soon subsided. The wound united by the first intention, and the patient became rapidly convalescent.

MISCELLANIES.

The Municipal Council of Paris has resolved to make considerable improvements in the hospitals of the capital, and more particularly as to that in the Faubourg St. Jacques, and that for sick children in the Rue de Sèvres. The first, though it contains 570 beds, is insufficient for the number of patients brought for admission; there is a want of water for baths, and the sexes and different classes of the inmates are not so divided as they ought to be. It is proposed to appropriate the House of Refuge in the Rue de l'Oursine, now vacant, as an additional receptacle. The hospital for children is so crowded that it is most unhealthy, and as a relief it is intended to place 700 beds in the Hospice des Orphelins, which is capable of holding so many, though there are at present only 180. It is further in contemplation to enlarge the Hospice Neckar. The Municipal Council has appropriated a sum of 350,000 francs for the expenses of these improvements out of the 600,000 francs allotted to the extraordinary expenses of the hospitals for 1834.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, January 2nd.

Henry Bird	Swansea.
Henry Hayman	Axminster.
James Whittaker	Bacop, near
	Rochdale.
John Wynne	St. Asaph.

LITERARY INTELLIGENCE.

Dr. Wilson Philip will publish a work on the Effects of Minute Doses of Mercury in Combination with the appropriate Treatment of various Diseases in restoring the Functions of Health.

BOOKS.

The Medical Quarterly Review, No. II., Jan. 1834.

We have not received the American Journal of the Medical Sciences, or the American Cyclopædia, though both were forwarded according to the letters of the Editors. There is the greatest irregularity in the delivery of the American journals, they do not reach us for months after publication.

CORRESPONDENTS.

Dr. Grant's Lectures.—We read a note from Dr. Grant in another Journal, disavowing his having sanctioned any one to announce the publication of his lectures on Comparative Anatomy, and the Journal, alluded to, copied the announcement from us, of course, without acknowledgment. Dr. Grant's memory must be very treacherous, as we copied the intelligence from the list of intended publications of Mr. Taylor, bookseller to the London University, and we think it a little strange that he should make the announcement without authority. We owe this acknowledgment to ourselves, and also to the *Lancet*, for though we are formidable rivals to that publication, we should not use any unfair mode of warfare towards it. And now let the other parties concerned to breakfast with what appetite they may.

Professor Davis's Lectures on Midwifery, at the London University.—We copied the lists of students at the University and King's College from the *Athenæum*, and the misrepresentation was made by a correspondent in that excellent journal. It was most unfair to state that the number of students attending Dr. Davis's class was 49, when it really was 98. So much for the veracity of correspondents.

Gracchus.—The Westminster Medical Society has redeemed its character, by rescinding the stultifying proceedings at the late meetings. The *Gazette* will be in ecstasies.

A Member of the Medical Society of London.—We did not insert the copy of the petition on Medical Reform, because the Society cannot sanction it.

A Staunch Reformer. The remarks are well deserved, but too caustic.

Dr. Ryan has removed his residence to No. 4, Great Queen-street, St. James's Park, Westminster.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publisher, 356, Strand, near King's College.

THE

London Medical and Surgical Journal.

SATURDAY, JANUARY 18, 1834.

VOL. IV.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

Delivered at the University of London,

Session 1832—1833.

LECTURE LXXII., DELIVERED MARCH 21, 1833.

GENTLEMEN,—When a sore is situated under the prepuce, and the latter is so swollen that it cannot be drawn back, and the sore examined, you should always be careful to wash the matter away, which is apt to collect under the foreskin. For this purpose, employ a solution of the acetate of lead or sulphate of zinc;—indeed, by attending to cleanliness in cases of this kind, you are doing a great deal towards the cure; and now that the plan of giving mercury in moderate quantities is generally preferred to a violent and profuse salivation, you would do no material harm by employing the mineral in this mild manner, even though the concealed situation of the sore might not let you judge of its exact character. In such a case, I should consider the exhibition of mercury in moderate, or what is called *alterative* doses, perfectly justifiable. Formerly, when the ulcer could not be seen, and when it was the custom to salivate the patient profusely, the question as to whether mercury should be given or not was a very serious one—it was virtually a question, whether the patient should or should not undergo a long and violent salivation; whether his constitution should be subjected to severe impairment or not; but now the decision does not involve a consideration of this importance.

There is one kind of chancre which occurs on the lining of the prepuce, reflected over the corona glandis, leading to an accumulation of pus between the skin of the *dorsum penis* and the *corpora cavernosa*. If you do not make an outlet for the matter collected in this situation, it will sometimes spread up to the pubes; several small openings will take place; but they will be insufficient, and the matter

may extend as far as I have mentioned. Sometimes a considerable part of the skin of the *dorsum penis* will ultimately be destroyed; and I recommend you, with the view of preventing such mischief, to make an early opening.

Many good practical surgeons do not place implicit reliance on the doctrine of the inviolable possibility of knowing whether a primary sore is venereal or not by its mere appearance; but, it may be the wisest maxim, when you are in doubt, always to give mercury in moderate quantities. Gentlemen, it is worth your while to remember one fact in this part of practice, namely, that the successful treatment of chancres in general materially depends on the kind of regimen observed by the patient; for if he neglect to keep himself quiet—if he expose himself to all weathers, and be guilty of excesses—he will be exposed to more severe consequences than other patients with similar complaints, who conduct themselves more prudently.

I need not enlarge upon the dressings proper for chancres in general; I observe, that astringent lotions usually answer better than greasy applications; and, when there is much inflammation around the sore, you should enjoin the recumbent position, which has a great effect in promoting the cure of sores on the genitals, whatever be their character. Experience will soon teach you that quietude has here vast influence, and that patients who avail themselves of it will get well in one-third of the time required for the cure of another patient who is constantly walking about, and going out in the damp cold air: he will also be much less likely to have secondary symptoms.

Gentlemen, let us next consider the subject of *buboes*. The venereal matter, or poison, in its passage through the inguinal glands, frequently gives rise to inflammation and enlargement of them, which, in many instances, is followed by suppuration and ulceration; the swelling, abscess, or sore, thus produced, is termed a *bubo*, a name derived from a Greek word signifying *the groin*; though, if the patient happened to have a primary venereal sore on one of his fingers, he might have a *bubo* just above the elbow, near the *ianet*

edge of the biceps, or in the axilla, so that a bubo does not always imply a disease in the groin, as the etymology of the word would imply. But, gentlemen, the poison of syphilis may make its way into the system, without exciting any inflammation in the absorbent glands of the groin, or other region of the body; no bubo at all may intervene between the occurrence of the primary sore and the commencement of secondary symptoms. In other terms, the latter are not invariably preceded by a bubo. On the whole, buboes form more frequently after a chancre on the prepuce, than after one on the glans; but do not set down every inflammation of the glands of the groin as venereal, for these parts are subject to various enlargements from other causes. Mr. Hunter observed, that when the venereal poison affected one of the absorbent glands, the gland that inflamed was one of the nearest to the primary ulcer. Such, indeed, is the fact; and you will not find that the absorbent glands, situated in the course of the aorta or iliac vessels, are ever inflamed, and brought into the state of suppuration by the absorption of venereal matter. The glands of the groin, then, may inflame, suppurate, and ulcerate, but not those within the trunk. Mr. Hunter entertained a suspicion, that another criterion of a venereal bubo was the circumstance of its involving only one gland; but, at the present day, this test is not relied on by any man of experience. Frequently, in venereal cases, several glands inflame; and sometimes in glandular swellings from irritation, only one gland is concerned. Also in a bubo, arising from scrofula, there may be only one gland affected at first; so that the distinction suggested by Mr. Hunter cannot, I believe, be depended upon. Another character, assigned by Mr. Hunter to a venereal bubo, is the quickness with which it generally proceeds to suppuration, and the shortness of time which the matter requires to make its way to the surface. I am afraid that this test, also, is not of much practical importance, for there is great variety in venereal buboes in this respect; some are much more indolent than others; and it is far from being the invariable character of a venereal bubo to proceed rapidly to suppuration; for while some of them are very acute, corresponding more or less to Mr. Hunter's description, others are of a chronic character; and this frequently cannot be accounted for, either by the influence of scrofula or mercury; the two circumstances which Mr. Hunter believed would generally explain the greater slowness of certain varieties of bubo than of the generality of them. In particular, he thought that the slowness of suppuration in some venereal buboes might be ascribed to the disease having taken place in a person of scrofulous habit, or else to mercury having already had some effect on the disease.

Gentlemen, you will notice, in practice, that most buboes, not truly venereal, are preceded and accompanied by more or less disorder of

the health; and, under such circumstances, if there should be no chance to account for the bubo, you would have ground for suspecting, that the state of the health had brought on the glandular enlargement. In relation to this subject, it is also my duty to apprise you, that when the patient will not admit that he has had a chancre, or you cannot discover any traces of one, it is a rule in practice, to inquire into the state of the nearest lower extremity, and to ascertain whether there is any inflammation, wound, boil, or sore about the foot, leg, thigh, or nates, any bunions on the great toe, any inflamed bursa, or painful corn; it is well known, that the inguinal glands are liable to inflammation and enlargement, in consequence of any of the causes which I have enumerated.

Gentlemen, in the treatment of a bubo, if it be a venereal one, you ought to be guided by the same principles, which I recommended to your attention when speaking of primary sores: the remarks I have delivered respecting the doctrine, that venereal primary sores may be cured without mercury, apply also to venereal primary abscesses and buboes. Although Mr. Hunter referred the efficacy of mercury to a specific action excited by it in the constitution, which action is represented as capable of subduing the venereal complaints; yet he entertained a particular opinion, with respect to the *modus operandi* of this mineral, in the case of a syphilitic bubo; for instance, he had a high opinion of the usefulness of getting the mercury to pass through the diseased gland, which usefulness, real or imaginary, must have been ascribed in part, at all events, to the direct influence of the mercury on the gland, in its passage through it; he believed, that in this way buboes were sooner cured than when mercury was differently exhibited; and it was, therefore a great object with him to rub the mercury upon a surface, from which absorbents proceeded to the gland affected. This practice is, perhaps, not deemed so essential at the present day, and some very good surgeons even think, that the irritation of the mercury will sometimes actually bring on swellings of the absorbent glands, or aggravate them if they exist. At all events I may state, that the plan is not universally approved, especially when there is acute inflammation about the glands affected. When, however, the swelling is of a more indolent or chronic nature, the practice of making the mercury pass through, or to the gland, or even of applying it to the groin itself, is frequently adopted; and there can be no doubt, that such method has an influence in dispersing the swelling. On the contrary, if the gland should be very much inflamed, and highly painful, the value of the practice is extremely questionable, and, as I have said, you will occasionally meet with practitioners of judgment and experience, who are decidedly adverse to it.

How long the use of mercury ought to be

continued in the treatment of buboes, and what is the quantity requisite to be given? are questions to which different replies would be made by the surgeons of different schools: I consider myself to be of that party, which, while it admits the possibility of curing all the forms of syphilis without mercury, fully admits the general usefulness and superiority of this mineral as a means of checking and eradicating the disorder; that it is the best means of lessening the risk of secondary symptoms, and of quickening the cure of many forms of the disease. But, for this purpose, I should say, that long continued and full courses of mercury are hardly ever requisite. In former times, when buboes yielded with tolerable celerity, it was the common rule to continue the mercury for about six weeks, at the end of which time it was entirely left off, and bark, sarsaparilla, and other tonics given. Such was the general plan, when buboes yielded in a moderate time. But, when they subsided very rapidly, then the mercury was given for at least three weeks or a month after the healing of the bubo. But, gentlemen, you will often find, that buboes will not heal after mercury has been persevered in for a long time, and more especially when the health is much disordered by it; I should say then, that after you have reason to believe that all specific action has subsided, and when you have reason to suspect that the mercury itself is seriously impairing the health, so that no salutary process can go on in the system, then mercury, which has already been given too long and too freely, should be discontinued without delay. Here the discontinuance of the mercury is necessary, and such other medicines given as are likely to produce an improvement of the general health. Too long a perseverance with mercury will often retard the cure of a bubo, —may, will sometimes so derange the constitution, that ulceration will spread from this cause alone, and assume a very dangerous condition.

Gentlemen, in scrofulous constitutions, either the influence of the mercury, or the derangement of the system, arising from the united effects of this mineral and of the disease together, will frequently give rise to scrofulous enlargements. When mercury is so employed for primary venereal sores, as to occasion a full saturation of the system, if there be a tendency to scrofula, this abuse of mercury will frequently act as an exciting cause of the latter disease, and its continuance be sure to render the patient's condition worse. Its further exhibition would change the scrofulous abscess into a foul spreading, ill-conditioned ulcer, or into a phagedænic sloughing disease, which might eventually prove fatal. Here the discontinuance of mercury is a *sine qua non* in any plan likely to be attended with benefit; and, instead of looking up to mercury for a cure, you should look to remedies of another description, namely, bark,

quinine, sarsaparilla, the diluted nitric or sulphuric acids, and narcotics, such as hyoscyamus, conium, opium, the acetate or muriate of morphia, &c. In some cases, also, it will be necessary to use such medicines as are considered to have a peculiar influence over scrofula, namely, iodine, or the carbonate of soda.

In the local treatment of a bubo, it is a good rule not to be in too great a hurry to open the swelling, unless you find the matter has a tendency to spread, and then the sooner it is opened the better. You will find, that the matter is not in the glands themselves, but in the surrounding cellular membrane. In common examples, the skin should be suffered to become thin before an opening is made, and then a puncture may be made with a lancet or double-edged bistoury, but if the skin should be much undermined by the matter, and separated from the subjacent parts, then some surgeons would prefer opening the abscess with caustic. In this manner, you might destroy some of the diseased skin, and leave a very free opening, well calculated for the ready outlet of the matter, and for obviating all risk of the formation of fistulæ and sinuses. One consideration in favour of not opening buboes too soon, is, that, after matter has collected within them, it may be absorbed again, as soon as the constitution becomes affected with mercury, and then no opening at all would be required. Gentlemen, when I was on the subject of suppuration, it was explained to you, that you would more frequently find the absorption of purulent matter illustrated in venereal buboes, than in any other kinds of abscesses. This fact, therefore, is a consideration in favour of not opening such abscesses too soon.

When the bubo is much inflamed, antiphlogistic treatment will be necessary, as well as mercury. Specific inflammations, if common only, you will find are not altogether out of the control of ordinary antiphlogistic remedies. You ought then to apply leeches, and cold evaporating lotions, as in common inflammations; or, if cold applications will not answer, use emollient ones, as poultices and fomentations. When a bubo becomes a sore, the local treatment must be regulated by the appearances, character, and condition, which the ulcer may exhibit. In relation to this subject, I have already given you general directions, when on the subject of ulcers, and I need not now revert to them. When all specific action has ceased in the bubo, the disease is of course only a common sore, or a sore of one of the characters which I have explained to you in a former lecture. Some buboes, when the patient has been taking a great quantity of mercury, will, after bursting, leave the skin in an undermined state, with callous and irregular edges. These are mostly obstinate cases, and will sometimes remain unhealed for months. So difficult is it to bring such ulcers into a favourable condition by common means, that some surgeons cut away the hard callous edges

of the skin, as a measure that at once removes one difficulty in making the parts heal. Instead of this plan, I prefer applying a strong solution of the nitrate of silver to the callous edges of the ulcer, or rubbing them freely with the nitrate itself. Then their hardness will gradually subside and disappear; but, in the event of the case resisting this mode of treatment, you will be justified in practising excision of the hardened and diseased edges of the ulcer. In this condition of a bubo, you will also find the liquor arsenicalis, given internally, useful. Change of air, and sea-bathing, will also frequently be of very essential service.

The next subject, gentlemen, is to the secondary symptoms of syphilis. Whoever pays close attention to this extraordinary disease, will generally remark, that, previously to the occurrence of secondary symptoms, the constitution is somewhat disordered, there is more or less fever present, accelerated pulse, headache, loss of appetite, pains in the shoulders, or other parts of the body, and inability to sleep; indeed almost all patients are particularly restless for two or three days before the appearance of any secondary symptom, before they complain of a sore throat, or perceive any traces of cutaneous disease about them. According to the Hunterian doctrines, when secondary symptoms take place (for as I have told you, it is uncertain whether they will take place or not, and a proportion of primary sores, considered to be venereal, are never followed by secondary symptoms) when, I say, the secondary symptoms come, Mr. Hunter observes, they are more disposed to occur in some parts of the body than in others. On this account, Mr. Hunter divides the parts affected into two orders, the first order containing those parts in which the secondary symptoms usually first show themselves, namely, the throat and skin; the second, including parts in which the disease produces its influence at a later period, as the periosteum and the bones, to which some surgeons now add a few other parts, the periosteum, and especially the testicle; for one form of diseased testicle occurs in patients, who have suffered severely from venereal complaints, and is considered a syphilitic affection. Then I should mention the iris, which ought perhaps to rank in the second order of parts. I believe that Mr. Hunter's opinion, respecting the throat and skin, agrees pretty well with general experience, and modern surgeons are inclined to accede to his doctrine in relation to them; however, you will find pains in the bones sometimes precede the sore throat and cutaneous eruption. I have seen nodes follow a primary sore as the first secondary symptom, and this has also been noticed by others. I once attended a medical gentleman, who had no sore throat, and no cutaneous eruption; yet he had nodes. It is generally considered that the average interval, between the primary and the secondary symptoms, varies from six to twelve weeks; but it may extend to several months, or according to some reports to one or

two years. Without undertaking to decide whether the last opinion be correct or not, I may safely say, that it admits of doubt, and that, generally speaking, the interval rarely exceeds three months. When we find that the same surgeons, who admit the possibility, and assert the occurrence, of an interval of two years, likewise admit the entrance of the poison into the system without the presence of any ulcer, or primary sore at all, we see in this circumstance a possible explanation of the late commencement of secondary symptoms in particular cases. These gentlemen suppose, that the virus may pass into the system without any ulcer at all, and this very assumption of course puts an end to the plausibility of the other opinion with regard to the possibility of so very late an occurrence of secondary symptoms. But, gentlemen, as I have already told you, in reference to primary sores, I may state, that the secondary symptoms rarely commence later than three months after the cure of the sore; sometimes they come on much earlier; nay even before the primary sore is healed. There are few surgeons who have not met with cases, in which there were at the same time an uncured chancre, an unhealed bubo, sore throat, iritis, and so forth, existing altogether.

The cutaneous eruption presents considerable varieties. A few years ago, it was considered that no eruption was venereal, unless it had a copper-coloured appearance, and was scaly. Mr. Hunter represents the skin as becoming mottled at first, and tells us that appearance will come out, and fade away again repeatedly. Now, this observation must have been overlooked by former surgeons, who endeavoured to prove that syphilitic symptoms invariably proceed from bad to worse; for here we find it stated, by their own great authority, that the eruption sometimes disappears and then returns; that the disease fluctuates; yet, the doctrine that Mr. Abernethy collected by his inquiries from all the most experienced surgeons in London, was, that the symptoms of syphilis are continually progressive; that when there is a sore, unless mercury be given, the sore would always become worse, and a true venereal eruption would never disappear. The true syphilitic eruption is said to be characterised by its being scaly, and of a copper or reddish-brown colour; small copper-coloured spots first showing themselves, and the cuticle then peeling off, desquamating, as the phrase is. Some of these blotches conjoin, so as to form extensive patches; but others of the same colour, and decidedly syphilitic, are, on account of their diminutive size and particular figure, sometimes termed the *lenticular* syphilitic lepra. The venereal eruption, according to Mr. Hunter, consists of copper-coloured spots on the skin, accompanied by desquamation, which leaves the subjacent cuticle thicker and thicker as this process goes on, and of the same colour as the cuticle

which peels off. If the disease advance further, scabs will form, suppuration will take place under them, and the result may be a secondary venereal ulcer, which, when thus produced, affects principally such parts of the skin as are in contact with other portions of the cutis, like the fold of the nates, the angle between the scrotum and thigh, or in the armpit. In these situations, the eruption, instead of being scaly, has a raised surface, from which a whitish matter frequently oozes. These scaly eruptions first appear on the face, hands, and wrist, afterwards on the breast and the extremities, where they are generally remarked to be particularly numerous, and to assume the form of lepra, or psoriasis. There is another circumstance deserving of attention, namely, when the palm of the hand or the sole of the foot, where the cuticle is very thick, is affected, an appearance is produced, constituting what is often termed the *syphilitic lepra* and *psoriasis* of the hands and feet. Mr. Carmichael, like Mr. Hunter, regarded this scaly copper-coloured eruption, as characteristic of true syphilis, and though, says he, there are other eruptions, which are venereal, or the consequence of venereal complaints, yet they are not truly syphilitic. He notices pustular, tubercular, and papular eruptions; but he does not consider these as consequences of a true Hunterian chancre, but refers them to primary sores of other descriptions. The syphilitic eruption, according to Mr. Carmichael, always consists of scaly blotches, in the form either of lepra or psoriasis, and unattended with fever; or I should rather say, there is not so much fever present with these eruptions as with either of the others, namely, the papular, the tubercular, or pustular. You are aware, gentlemen, from what I have already explained, that Mr. Carmichael attaches so much importance to the form of the eruption, that he considers it possible to tell by the inspection of the cutaneous disease, what has been the character of the primary sore. In short, he divides the venereal disease into four species or varieties. The first of these is the *scaly venereal disease*, or that which is correspondent to the Hunterian description, the chancre having a hardened edge and base, and when the bones are affected, their shafts and harder parts chiefly suffering, the nodes being true ones, and the eruption scaly, in the form either of psoriasis or lepra. The second is the *papular*, so called from the character of its eruption, which may follow gonorrhœa, and what some surgeons call the *gonorrhœal ulcer* of the prepuce and corona glandis. The third is the *tubercular*, as being attended with an eruption of this character; and the fourth is the *pustular* variety of the venereal disease, so called also from the appearance of the cutaneous affection. But, as I have already informed you, this doctrine does not gain much ground in London, where the most experienced surgeons do not find sufficient

correspondence and uniformity between the primary and secondary symptoms of syphilis to admit of the views which I have been mentioning to you. In fact, Mr. Carmichael's doctrines suppose the existence and operation of a plurality of poisons; but, if such be partly the truth, we are scarcely yet prepared for its reception; nor will it account for many perplexing phenomena exemplified in venereal cases.

Secondary venereal ulceration is often preceded by an eruption, some part of which, after repeated desquamation and scabbing, is converted into sores; but in other instances, chronic inflammation of the skin takes place, independently of any eruption, and ulceration follows; and occasionally inflammation, suppuration, and secondary venereal ulceration, will occur over nodes. Secondary venereal ulcers have not any regular and constant appearance; sometimes they are superficial, of a round shape, of a chronic character, and disposed to heal favourably; others evince the peculiarity of healing in the centre and extending at the circumference, the unhealed part being of a tawny colour, with sharp edges, and a foul bottom. An experienced surgeon, immediately he sees an ulcer of this kind, will be led to suspect its venereal character; its tawny appearance, its shape, and its situation, will induce him to entertain a suspicion, that it has been preceded by other venereal complaints. But you must not conclude, from the mere look of a sore, that it is certainly venereal; always take into consideration the history of the case, before you give a positive opinion.

Besides these secondary symptoms, I must not omit to specify the ragged ulcerated fissures and clefts seen on the nates, or about the anus, and especially in the fold at the lower part of the nates, and between the perineum and the thigh, or sometimes even about the roots of the finger nails. In the latter case, matter forms under the nail, which becomes detached; this case is called the *venereal whitlow*, the discharge from beneath the nails being remarkable for its strong, fetid, and peculiarly disagreeable smell.

I may also notice, as an accidental occurrence, the production of *warts*: in some works on the venereal disease, you will find a description of warts, which occur in the situations where there has been a previous sore. If my own judgment can be trusted, I never saw any warts which were really venereal, if the effect of mercury be taken as a test, which, to be sure, is a very fallacious one; at all events, I have never seen any warts which could not be cured either by excision, by ligature, by caustics, or by stimulating treatment, and no bad consequences ever followed, though mercury was not given. I am not surprised, therefore, to hear of surgeons renouncing all idea of any warts being of a venereal kind. Some warts, occurring in venereal patients, acquire a large size, especially in women, and

receive the name of *condylomata*. Formerly it was the practice to salivate patients for the cure of these excrescences, and this sometimes more profusely than for a sore throat or a chancre; and it must be acknowledged, that when the system was thus brought and kept under the influence of mercury, the warts generally diminished, and were ultimately cured; a circumstance that confirmed the idea entertained by the old surgeons, that they were truly venereal. It was exactly on the same principle that a decision was commonly made in former days about the character of many other symptoms; and when they yielded to mercury, they were pronounced to be venereal; yet it was known at least thirty years ago, that warts could be as permanently and certainly cured by the knife, ligature, escharotics, and stimulating applications, as by the employment of mercury; and what is still more to the point, it was known that the cure was radical. On what principle, then, could the severe measure of a long and profuse salivation be vindicated?

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833-34.

LECTURE IV.

Pathology and Treatment of Gastritis.

GENTLEMEN,—You recollect that at our last meeting I endeavoured to lay before you some of the general facts connected with the pathology of gastritis, and showed you that the statement made by Broussais, that inflammation of the mucous membrane of the stomach is always accompanied by a similar affection of some part of the intestines, has not been confirmed by the investigations of more recent observers; but, on the contrary, that their experience goes to disprove, in various instances, the validity of this assertion. But, when I say that this statement has been disproved, it is only as taken in the general and extended sense. The fact of their frequent co-existence has been proved;—the statement that they are always associated has been found incorrect. Another thing connected with this, which has been also established by repeated observation, is, that the cases in which they are commonly combined are those in which a secondary affection of the mucous surface of the digestive tube comes on during the course of a fever; so that, if in fever a gastritis supervenes, you will commonly have enteritis; or if the fever be complicated with enteric inflammation, the mucous surface of the stomach will partake in the diseased action.

I have described some of the more prominent symptoms of gastritis, and directed your attention not only to the ordinary symptoms,

as mentioned in books, but also to others which have either been passed over, or slightly noticed, by authors; as for instance, dysphagia, oppression and sense of constriction about the præcordia, globus, pains relieved by cold and acid drinks, &c., and that obstinate hiccup, which, in cases where there is reason to suspect gastritis, marks inflammation of the cardiac orifice of the stomach. I stated, that hiccup alone does not prove the existence of inflammation of the cardiac orifice of the stomach, unless where symptoms, indicative of gastric inflammation, prevail at the same time. I laid before you the actual state of the case with respect to the value and certainty of diagnosis, as derived from an inspection of the tongue; and showed you that no reliance can be placed on it, since it has been proved that we have the most opposite conditions of the digestive tube accompanied by a similar condition of the tongue; and that there is no peculiar modification of the one corresponding exactly and constantly with any peculiar modification of the other. The conclusion to be deduced from these facts is, that in the treatment of inflammatory affections of the digestive tube, we are not authorised, and would frequently err, in taking the tongue alone as our guide in practice; and you may lay down this as a rule, and an important one:—if we look through the whole range of the history of medicine, we shall scarcely be able to point out any symptom which, taken singly, is decidedly indicative of any one particular condition of an organ. You will find that this proposition is not only extensive in its scope and relations, but also of extreme value in its application. You will commonly hear persons saying, this is such a disease for this symptom is present, and that is such a disease for such a symptom is extremely well marked. But there is no single symptom which points out, with certainty, any peculiar condition; and to arrive at a just and well-grounded diagnosis, you must always take the whole group of existing phenomena, connect the lights which they collectively throw upon the case, and then make a cautious decision. It may be objected to this, that there are particular signs, as, for instance, the stethoscopic, which point out distinctly particular states of organs. It is said that *gargouillement* is decidedly indicative of a phthisical cavity, that *ærophony* points out a particular stage of pleuritic effusion, and that *metallic tinkling* is an unequivocal proof of pneumothorax. This, however, is not the fact; even in these cases you are not authorised to depend on any sign or symptom taken alone. If you ground your decision on any individual sign, you will very often fail in arriving at the truth.

I showed you that the sympathetic irritation of gastritis varied according to the peculiar character of the disease, and the habit and degree of susceptibility of the patient; that, generally speaking, the more intense the disease is the more numerous are its irritations,

but that, in all cases, they are considerably modified by predisposition (I use this term for want of a better), the sympathetic irritation being reflected on the lungs in cases where these organs are naturally unsound, and on the brain, where the patients have a tendency to disease of that organ. I endeavoured, also, to impress on you the fact, that these irritations are at first functional; but when long continued or marked by extreme severity, they are very apt to terminate in organic disease. I illustrated this point by several examples:—I shall give a few more of this kind before I enter on the treatment of gastritis.

If a patient labouring under acute gastritis has bad cough, if respiration be very much hurried, and the distress of the chest great, and that these symptoms are overlooked or neglected, you will find that the cough, which was at first only a result of functional disease, will at last point out an organic affection of the lung. Again; let a patient labouring under gastritis have severe headach, restlessness, and irritation; suffer these symptoms to go on and increase in violence, and the great probability is, that they will terminate in arachnitis. The obvious deduction from these facts is, that when a sympathetic irritation has existed for some time in a state of considerable intensity, it is very probable that there is more or less of organic derangement produced, and we are not to expect to be able to remove it by merely attacking the original seat of the disease.

The last great rule which I endeavoured to impress upon you was, that where these sympathetic irritations, these affections of the nervous, respiratory, and circulating systems were extremely well marked, the ordinary local symptoms were more or less wanting, but that this does not by any means imply the subsidence of the original disease. This is a most important law in pathology.

In my last lecture I entered into a detail of the sympathetic irritations connected with the brain and other parts of the nervous system; to-day we shall consider the sympathetic relations, as connected with the viscera of the thorax. If you look to the cases of acute gastritis, mentioned in works on toxicology, you will find that in cases of gastritis, produced by swallowing corrosive poisons, the patient has often frequent hard cough, the breathing is at first hurried, then becomes protracted and laborious, and that death is generally ushered in by tracheal rattle. The same symptoms are observed in cases of acute idiopathic gastritis; hurried breathing, extraordinary hard and almost laryngeal cough, sometimes occurring in paroxysms, sometimes constant. For the first few days it is, generally speaking, dry; as it progresses, there is more or less expectoration. At first it is the result of sympathy; there is as yet no organic affection of the respiratory system, and the disease is purely functional; still it is of importance, and entitled to your particular attention, be-

cause in consequence of the apparent identity of the symptoms, it is often mistaken for disease of the substance of the lung or its mucous lining. The existence of a gastritis is frequently overlooked; the ordinary symptoms of pain in the region of the stomach, tenderness on pressure, and thirst, are overlooked, and the sympathetic relations alone are attended to. Observe what mischief may result from this error. The treatment of acute affections of the lining membrane, or parenchymatous tissue of the lung, is very different from the treatment of a gastritis. In the one case bleeding is necessary; in the other, its efficacy may be doubtful, or the practice even dangerous: in one, tartar emetic is one of the best and most expeditious means of effecting a cure; in the other, the use of antimonials has the worst effect. It will strike you that in such cases percussion and the stethoscope are of inestimable value. You are called to attend a patient in fever, you find he has cough, hurried breathing, and perhaps pain in the chest; from a consideration of the history of the case and the primary symptoms, you have reason to think the case is one of gastritis, and you wish to know whether the symptoms be purely sympathetic, or caused by organic disease of the lung. In such a case, a person without a knowledge of the stethoscope is completely helpless, and unable to decide the point. This, I assure you, gentlemen, is a very common case, and should be a strong inducement to the study of the stethoscope. What advantage does a knowledge of the stethoscope give? It leads to the formation of an accurate diagnosis; it points out either that there is no disease in the lung, or if there be, that it is not sufficient to account for the symptom, and therefore that you should look for its cause in some other situation. You find a person with laboured and rapid breathing, perhaps fifty or sixty in a minute; you are struck with the apparent lesion of the respiratory system, but on percussing the chest and using the stethoscope, you find the respiration perfectly clear, or perhaps a slight bronchitis, insufficient to account for such violent symptoms. Where such phenomena are observed, you will often find that they are connected with a gastritis, particularly where there is fever and the local signs of a gastric inflammation. I can tell you, from a most extensive experience, that in such cases you can inform the patient's friends, that the most sudden and decided relief will be experienced from the use of iced water, and the application of leeches to the epigastrium. You can have hardly an idea of the rapidity with which all the symptoms of pulmonary irritation are removed by this practice. Cases of this extraordinary sympathetic irritation are very common in children, but you will also frequently meet with them in adults.

I have been called to decide the question, whether a disease was pneumonia or gastritis, where there was a difference of opinion between two practitioners. Now, it is very

easy to come to a proper decision in such cases. There is one point which you should always hold in view, and that is, the *length of time the symptoms have lasted*. If symptoms of pulmonary disease have been going on for four or five days, and at the end of that time you find that there is no perceptible organic disease of the lung, you may be certain that it is gastric irritation; because if it were organic disease of the lung, it would have shown itself before that time, and could be detected by percussion or by the stethoscope. We have had many cases of these sympathetic irritations of the lungs in the Meath Hospital, which recovered under the treatment for gastritis, and where the patients, by some excess or error in diet, brought on the pulmonary symptoms again, and they were removed a second time by putting them on a low diet. Before I quit this subject, I wish to make one remark by way of caution. When you have discovered the existence of these sympathetic irritations, you should not be thrown off your guard, and consider them only as functional affections. You should examine the next day and the day after, for you may find that in a very short space of time actual disease of the lung has taken place. You should be therefore watchful, and never omit making a daily examination; for if the sympathetic irritation be severe, it is very apt to run into actual organic disease.

Gentlemen, we now come to speak of the treatment of simple acute gastritis. Here there are three principal indications. One of these is to remove inflammation as speedily as possible. You cannot, as under other circumstances, leave this disease to nature; the organ affected is one of the utmost importance to life; and if you do not cut it short at once, a typhoid state comes on, to which the ordinary and efficient means of antiphlogistic treatment are inapplicable. The first indication then is to cut short the inflammation as speedily as possible. The next thing is to prevent the introduction of any thing into the stomach which will excite the physiological action of that viscus. You are aware that while the stomach is engaged in the process of digestion, its vascularity is very much increased, and that this, which in health is merely a physiological condition, is unaccompanied by any kind of danger. But in a state of disease it proves a source of violent excitement, and superadds very much to the existing inflammation. You must, therefore, be extremely cautious with respect to what enters your patient's stomach, and carefully remove every thing capable of adding to the excitement which always attends gastritis. The third indication in the treatment is to modify and remove the sympathetic or secondary irritations.

Now I shall suppose that we have to treat a case of simple acute gastritis not produced by the swallowing of corrosive poison or indigestible food. Here we have a patient labouring under violent inflammation of one of the most important organs in the body; and the

question is, are you to adopt the ordinary and usual mode of stopping inflammation by opening a vein in the arm? I must here state, that we are very much in want of a series of well-established facts to guide our practice on this point, and to inform us how far general bleeding is useful in acute inflammation of the stomach. At the present period, the question is by no means settled, and the practice is uncertain. I believe, however, that when we are called in at an early period of the disease, where the patient is young and robust, the stomach previously healthy, the fever high, and the pain great, we may have recourse to general bleeding with advantage; bearing this in mind, however, that you are not to expect to cut short the inflammation by the use of the lancet. Inflammations of the mucous membrane of the stomach and bowels, and perhaps of the lungs, are not to be overcome at once by the lancet; the only cases in which you can expect to cut short an inflammatory attack are those in which the parenchymatous tissue of an organ, or its serous membrane, is affected. This is a general and important law. You will often be able to cut short a hepatitis or a pneumonia by a single bleeding, but you will not by the same means be able to repress a bronchitis or an inflammation of the mucous membrane of the intestines. If you bleed in gastritis, bleed at an early period; not too largely, or with the expectation of cutting short the inflammation, but in order to prepare your patient for the grand agent in effecting a cure—local bleeding. This is the principle on which you are to employ the lancet.

In the treatment of gastritis there is nothing more useful, nothing more decidedly efficacious, than the free and repeated application of leeches, whether the case be idiopathic, or produced by the swallowing of a corrosive poison. In this treatment of acute gastritis, you will frequently see, perhaps, the most striking instances of the rapid and decided utility of medical treatment; you will see the vomiting subside almost immediately, the epigastric pain and tenderness disappear, the cough and headach relieved, the fever subside, and the tongue change after the application of leeches. To remove the symptoms, the best and most effectual means are leeches; and these must be applied again and again, according to the duration and obstinacy of the symptoms. Here I wish to make one remark of importance. From an opinion very prevalent in former times, that pain and inflammation were inseparable, the older practitioners thought that when the pain ceased the inflammation also ceased; and hence many of our predecessors, and I fear some of our contemporaries, never think of re-applying leeches, no matter what the existing symptoms may be, if pain has been relieved by the first application. Nothing is more erroneous than this practice. It frequently happens that the pain and epigastric tenderness are removed by the first application of leeches, but the breathing

is still quick, the fever high, and the thirst ardent. So long as these symptoms remain, the inflammation of the stomach is still going on. The mere subsidence of pain or tenderness of the epigastrium should never prevent us from resorting to the application of leeches. In leeching the belly for inflammation of the stomach or bowels, it is a common practice to apply a poultice over the leech bites, with the view of getting away as much blood as possible. I am not inclined to approve of this practice. The weight of a poultice is frequently troublesome, and the heat produced by it disagreeable; the patients desire cold, and for this purpose they will often throw off their bed-clothes, feeling a degree of relief from exposing the epigastrium to a stream of cool air. Some practitioners have applied pounded ice over the stomach with good effects, as we see it frequently applied to the head with the same results in cases of encephalitis. Again, the application of poultices causes an oozing hæmorrhage, the amount of which it is impossible to calculate, which is often hard to be arrested, and which, in debilitated persons and children, has the effect of lessening the powers of life without removing the original disease. It is much better to leech again and again than to do this. Where there is not much epigastric tenderness you may apply a cupping-glass over the leech bites with advantage, as you can get away as much blood as you choose, and the tendency to after-hæmorrhage from the leech-bites is diminished by the application of the cupping-glass. In very young subjects the tendency to obstinate hæmorrhage from leech-bites is so great, that many practitioners are afraid to use leeches, and I believe some children have been sacrificed to this fear. The best mode of managing this is, if the leech bites cannot be stopped by the ordinary means (and in very young children they seldom can), to stop them at once by the application of caustic. Do not lose time in trying to arrest the flow of blood with flour, or lint, or sticking plaister; wipe the blood off the bite with a piece of soft dry lint, plunge into it a piece of lunar caustic scraped to a point, give it a turn or two, and the whole thing is settled; and you can generally go away with the agreeable consciousness of having prevented all further danger, and without being uneasy lest your patient should bleed to death in your absence.

With respect to the management of the bowels in acute gastritis, a few observations will suffice. You will always have to obviate the effects of constipation; both in the acute and chronic form of the disease there is always more or less constipation; in fact, the same condition of the bowels is generally observed in both. Now, if you attempt to relieve this constipation in acute gastritis, by administering purgatives, you will most certainly do a vast deal of mischief. Nothing can exceed the irritability of the stomach in such cases; the mildest purgatives are instantly rejected, even cold water, or effervescing draughts are often

not retained, and a single pill or powder is frequently thrown up the moment it is swallowed. Under such circumstances, it is plain that the administration of purgative medicine is totally out of the question. Even though the stomach should retain the purgative, you purchase its operation at too dear a price; for it invariably proves a source of violent exacerbation, kindling fresh inflammation in an organ already too much excited. In this state of things the best thing you can employ to remove constipation is a purgative enema, repeating it according to the urgency or necessity of the case. Where there is no inflammation in the lower part of the intestinal canal, you may employ injections of a strong and stimulating nature, with the view not merely of opening the bowels, but also of exercising a powerful revulsive action. I shall mention here an interesting fact, proving that stimulant injections have a decided revulsive effect; and that their influence extends not only to other portions of the intestinal tube, but also to distant parts of the system. In South America, where, from the heat of the climate, and the prevalence of bilious affections, sick headach is a very common and distressing symptom, a common mode of cure is to throw up the rectum an extraordinary enema, composed of fresh capsicum, and other aromatic stimulants. The irritation which this produces acts as a very efficacious and speedy revulsive, causing the almost immediate removal of the cerebral symptoms.

In those cases of gastritis, where not only purgatives, but even the mildest substances are rejected, the plain common sense rule is to give nothing. Where cold water is borne by the stomach it may be taken in small quantities, as often as the patient requires it. Solid ice, too, may be given with decided benefit. There is a mistake which prevails with respect to the employment of ice in gastritis, which I wish to correct. Some persons object to its use, and reason in this way:—persons who have taken a quantity of cold water, or ice, when heated by exercise, have been frequently attacked with gastritis and fever, and consequently the use of these substances must be attended with danger in case of gastric inflammation. This, however, is false reasoning; you need not be afraid to order your patient ice ad libitum; depend upon it, there is no danger in employing either ice or cold water in gastritis. There is nothing so grateful to the patient as ice. Let a quantity of it be broken up into small pieces about the size of a walnut; let your patient take one of these pieces, and, having held it in his mouth for a few moments to soften down its angles, let him swallow it whole. The effect produced by this on the inflamed surface of the stomach is exceedingly grateful, and the patient has scarcely swallowed one portion when he calls for another with avidity. It will be no harm, gentlemen, if I should here mention to you a secret worth knowing. There are few things so good for

that miserable sickness of the stomach, which some of you may have felt after a night's jollification with a set of pleasant fellows, as a glass of ice; Byron's hock and soda-water are nothing to it.

After the first violent symptoms of the disease have been subdued, I believe the very best thing which can be given is cold chicken broth. The point which we are always to keep in view is to remove inflammation from the stomach, and this should regulate the use of every thing taken into the stomach. I believe we might derive much advantage from anodyne injections in gastritis. I cannot say that I have ever employed them in such cases; but if I were to reason from their utility in other forms of abdominal inflammation, I should be induced to look upon them as entitled to some consideration. There is another point to which I will briefly advert. In the treatment of acute gastritis, there is nothing more commonly used than effervescing draughts; yet I have frequently seen them produce distinct irritation of the stomach. In cases where gastric irritability is excessive, I would not advise you to give effervescing draughts, or if you do, watch their immediate effect; see how the first one has agreed with the stomach before you venture to give any more. Patients labouring under this disease should be kept extremely quiet, as frequently a slight motion brings back the vomiting. Every thing which is swallowed should be in small quantity; a large quantity of any substance frequently causes a return of the vomiting, by distending and irritating the stomach. One of the best things you can give, and the best way of giving it, is iced lemonade, giving a tablespoonful from time to time. The extremities, which are generally cold in cases of intestinal disease, should be swathed in warm flannel.

I shall mention here a rule which should be carefully observed in the after treatment. A patient has recovered from the violent symptoms of the disease; the fever, thirst, pain, epigastric tenderness, and sympathetic affections have subsided; but he still is confined to bed, and in a state of great debility. Some patients under these circumstances have been unfortunately lost by allowing them to sit up in bed, or on the night chair. The nurse will sometimes, through ignorance, suffer a patient, thus enfeebled, to risk his life by sitting up in bed; sometimes during the course of the night she is overcome by sleep; the patient has a call to empty his bowels; and not wishing to disturb her, attempts to get up, and is found in some time afterwards sitting on the night chair quite dead. This is an unfortunate termination for the physician as well as the patient. A German author, Hoffmann, has written a treatise on the danger of the erect position after acute diseases; and in the course of the work, which is a very interesting one, he cites numerous instances of its bad effects. Not very long

since, a patient was lost in the Meath Hospital by the nurse allowing him to sit up after a severe attack of enteritis. Such also was the melancholy cause of death in the case of the late Mr. Hewson, one of my best and earliest friends: He got a severe attack, which was subdued with difficulty, and his convalescence was doubtful and protracted. One night, in the absence of his attendant, he got up for the purpose of emptying his bowels, and was found some time afterwards on the night chair nearly dead. He was immediately brought back to bed, and the necessary means employed to relieve him, but without much benefit, for he never recovered the effect produced on his debilitated frame.

CLINICAL LECTURES ON SURGERY,

DELIVERED

At the Hôpital de la Pitié, Paris,

BY M. LISFRANC;

Principal Surgeon to that Hospital.

TRANSLATED BY MR. H. RUSH,

Late Clinical Clerk to Dr. Elliotson at St. Thomas's Hospital.

Du Touchez, or Vaginal Examination.

THE general rules for examination per vaginam are sufficiently understood. We know that, in general, it is performed by the index finger, lubricated either with lard or some other mucilaginous substance, applied along the perineum, and is passed into the orifice of the vagina, near its posterior commissure, in order to avoid coming into contact with the clitoris; the woman should be in the erect position, so as to allow a descent of the uterus from its own gravity, and clad so that you might not hurt her feelings of modesty. But there are numerous details which are still left in oblivion, which I shall endeavour to describe. Thus it is not indifferent to lubricate the finger with cerate, with oil, or with butter, particularly when the examination precedes the application of the speculum; the ointment conceals the parts; butter, unless it be previously melted forms lumps, which might be mistaken for some morbid secretion; oil, therefore, is preferable in all cases.

In some women the situation of the neck of the uterus is so high, that the finger can reach it with difficulty, which frequently results from the great size of the external labia in fat women; and in such a case it is important to place the woman in an inclined position (about 25 or 30 degrees), as for the operation of lithotomy, or at the edge of a bed, with the legs abducted, or separated, and the feet supported by two chairs; the operator must then place himself between the thighs, and separate with care the labia majora, so that his hand might immediately come to the orifice of the vagina, gaining thus nearly an inch.

It is in these cases especially that it is necessary to apply with precision the general rule, which prescribes to place the thumb, extended, in an abduct direction, or separated between the external labia, the middle ring and little fingers equally extended and abducted from the index finger, between the buttocks and against the perineum, which the middle finger can raise a little; at the same moment we request the patient to bear down, and, with the left hand placed against the hypogastrium, the operator endeavours to press the viscera upwards, and subsequently the uterus downwards. Sometimes it is also necessary to desire the woman to walk about an hour or two previous to the examination. I have contrived by this means to lower the position of the uterus in a patient, who was in the ward of Saint Augustin, who had a polypus at the neck of this organ, the pedicle of which the finger could not attain before I adopted this precaution. In cases still more difficult, it is advisable to introduce both the middle and index fingers together, and, in some cases, the entire hand may even be introduced. The vagina at other times, though the woman be pregnant, or near the time of parturition, is sufficiently distensible to allow of its admission; but then it is necessary to proceed with much caution and slowness, and also to follow closely the rules that are laid down for the introduction of the speculum; setting aside the difficulty of the introduction of the whole hand, this method is preferable to the examination with one or two fingers.

In the ordinary mode of examination you must, as the finger penetrates, examine the whole vagina attentively; and, in order to do this, you must proceed from below upwards, performing a half circle with the finger around the walls of the vagina. It is now six years ago, that, from having neglected this precaution, I was deceived in a woman from St. Germain's. I examined for a long time without discovering a polypus, about the size of a nut, which had implanted itself in the middle and posterior part of the vagina.

In scrofulous women, on pressing the finger backwards, and on the sides of the vagina, we sometimes feel a crepitation produced by some of the lymphatic ganglia either in a state of induration or inflammation, which gives rise to symptoms analogous to those of other diseases of the vagina and uterus; it is sufficient for me to warn you of this error, to prevent you from falling into it.

But it is especially the examination of the neck and body of the uterus that demands great dexterity, and a perfect knowledge of all parts of this organ. It is essential to perform the examination per vaginam with both hands, if it be necessary to examine the circumference of the uterine neck; in fact, the extremity of the finger introduced can touch readily the vagina and the neck of the uterine organ to the extent of half of its circumference, but, in order to examine its whole circumference, the

arm must make on itself a complete movement of rotation, a thing that is impossible; there would be then, if the surgeon examined only with one hand, half of the vagina and neck of the uterus in contact with the nail of the finger; thus it is evident that the exploration would be very incomplete.

The uterine neck presents an infinite number of varieties, not only differing in different women, but in the same woman at different periods; it presents different characters, and it is of great importance not to confound the normal conditions with the pathological ones. It would be impossible here for me to indicate them all;—extensive experience on the living; and examinations on the dead, will give you much better information than all the doctrines I can advance. At the menstrual epoch, and even some days afterwards, the uterine neck is softer and more voluminous than ordinary; it presents the same sensation to the finger as in the second month of pregnancy; it is in the same state after frequent sexual intercourse; during this epoch, and even a short time before and after menstruation, the mouth of the uterus is sufficiently dilated to admit the first phalanx of the finger, which, on introduction, comes into contact with a smooth tissue, like serous membrane. In all cases, then, we should be cautious in coming to a conclusion.

At all other times, dilatation of the neck of the uterine organ indicates a serious disease, either existing or impending. If the finger, on introduction, instead of feeling a smooth and polished membrane, receives the impression which would be given, for example, by the mucous membrane, there is certainly some disease. We find, again, the neck as greatly dilated in size, from hæmorrhage or from a polypus, but in these cases other symptoms present themselves to elucidate the diagnosis.

There are some women in whom the uterine neck naturally presents the form of an elongated cone, the summit of which is directed downwards, with a round orifice, as if made with a gimlet; its length varies from an inch to an inch and a half. Hence the indications adduced by certain accoucheurs on the obliterations of the neck of the womb, at different periods of pregnancy, are subject to numerous exceptions.

In like manner also it is necessary not to mistake for pathological conditions the cicatrices resulting from laceration of the uterine neck at the time of parturition. These are hard, linear, and give the sensation of a very thin small plate, on the edges of which the two lips of the wound have united.

Lastly, in old women the neck of the uterus becomes more atrophied and contracted, even still more than the uterus itself; the vagina contracts itself around the neck, and presents in its lower portion a cul de sac.

Finally, the neck frequently projects either forwards or backwards, without being in a morbid condition; the tumefaction and the sensibility alone give sufficient symptoms

toms for a true diagnosis. Thus all women who have had frequent sexual intercourse, have the uterine neck thrown backwards, with a slight antiversion of the womb, which arises from the circumstance, that in coition the glans penis is lodged in front of the neck, which it thrusts upwards, but more particularly backwards. It is well known, that when from obliquity the neck of this organ does not permit the operator to touch it conveniently, he may, by changing the position of the patient, bring the uterine neck to a more or less favourable direction.

Other precautions are necessary, in order to examine the body of this organ.

It has been the opinion of some anatomists, but certainly an incorrect one, that the width of the superior portion of the vagina is less than the inferior; M. Cruveilhier has shown the superior is much the widest. This fact is important for the description of examination. In fact, if we limit ourselves to explore the vagina from below upwards, it soon reaches the attachment of the vagina round the neck; the finger on arriving at this junction will be impeded, and the examination of the body will appear impossible; but the width of the vagina permits us to push up its parietes a sufficient height to examine in most cases the inferior half of the body of this organ.

We may subjoin here to the examination per vaginam, the exploration by the rectum and hypogastrium. The examination by the rectum requires considerable experience; the uterus can be felt here only through the recto-vaginal septum, and gives a sensation as if the organ was of an enormous volume, which it is necessary to know in order to appreciate its just value. Thus we can examine the inferior half of the body of the uterus; and the broad ligaments of this organ are very distinctly felt through the intestinal wall, and much more so than by examination per vaginam.

There exists still greater difficulty in the examination per hypogastrium; but it is scarcely of any use unless combined with the examination per vaginam, in order to balance the uterine organ and appreciate its volume. Nevertheless greater advantage may be obtained by the combination of both of the examinations.

The dimensions of the body of the uterus are as variable as those of the neck; we therefore readily conceive of what importance it is to judge correctly, when a slight difference of volume may counter-indicate an operation in all other respects necessary. In general, every irritation in the vicinity of the uterus determines the blood to this organ, and consequently augments more or less its volume; and the more so, if the neck of this organ be itself seriously attacked. Extra-uterine pregnancy causes in it an augmentation of nearly a third.

I have already stated that the uterus is atrophied in old age. If, therefore, the uterine neck should require an operation, at the same

time the organ itself appearing to be more developed than at the adult period, it is a sign of considerable tumefaction, and the operation must be postponed.

The position of the uterus also varies, and the cause of it frequently remains obscure. In women who have borne children, its situation is lower; and in those who have frequent intercourse, its place is more anterior, this circumstance coinciding with the deviation of the neck of this organ backwards; and as regards more considerable displacement, which many practitioners describe as a particular disease, I believe to be nothing more in general than a symptom of swelling or engorgement, at least I have hitherto found no fact to contradict this doctrine. Since the slightest extension may in the normal state cause the ligaments to yield and displace this organ, why should not those very same ligaments yield under the weight of the organ, augmented by engorgement? A word more in conclusion, upon the accidents subsequent to the examination per vaginam. There are women, principally from the country, whose genital organs, although healthy, are endowed with such a degree of sensibility, that the least contact determines a painful excitation, and occasionally even produces fits of hysteria and convulsions. Baths, narcotic glysters, and bleeding have succeeded in calming this irritability. When such extreme sensibility is produced after an examination, the same means must be resorted to.

Introduction of the Speculum.

When we wish only to judge of the volume, the consistence, or sensibility of the uterine neck, the finger alone is sufficient, without doubt; but to discover excoriations, miliary eruptions, and the extent and nature of advanced ulcerations, it is necessary to have recourse to the speculum.

I prefer myself the one invented by M. Récamier, with a tin tube slightly conical, and furnished with a round-headed mandril by M. Mélier; but since the ordinary length (five inches) is not sufficient for all women, I have extended its dimensions to seven inches, and reject altogether either the curved or straight handle, which is no more than four or five inches in length, the utility of which is still to be discovered. The handle, fifteen lines in length, is more than sufficient for the action of the instrument, and makes it also more portable. There are besides these speculums of different diameters, designated by the numbers one, two, and three.

Before I describe to you the method of introduction, a few remarks on the surgical anatomy of these parts will not be unprofitable. The external orifice of the vagina, at least in women who have never borne children, is not in the same direction with the vagina itself; the posterior demi-circumference of this opening is formed by a transverse fold, flattened from above downwards, which constitutes by

their reunion the skin and mucous membrane. This fold, which is called the fourchette, varies in different individuals; but the more considerable, as there is more space between the rectum and the vulva, and consequently leaves below, and a little posterior, a small sac formed by the inferior and posterior parts of the vagina. Therefore, if we present the speculum in the direction of the vagina, we tend to destroy this fold, and consequently have here an obstacle causing excruciating pain, without enabling us to succeed in its introduction. It is then necessary to commence by directing the instrument from before backwards, and slightly from below upwards, following a line which would lead from the vagina to the summit of the cervix; and when it comes in contact with the lower portion of this sac, the operator must raise the instrument, as if he wished to come in contact directly with the sacro-lumbar articulation.

The dimensions of the external aperture of the vagina are likewise very variable. In virgins it is partly closed by the mucous membrane (hymen), which it is very necessary to respect, unless you have a positive indication of disease; besides, it is important that you should know, in young girls, the orifice of the vagina is exceedingly dilatable; much more so than in adults; after the cessation of the menses, the rigidity of this orifice continues to increase, so that in a very advanced age, instead of feeling a soft ring yielding under the fingers, we find it hard, and cracking at the least effort made to overcome its resistance; sometimes it admits with difficulty the little finger; and the vagina itself, instead of its customary wrinkles, offers smooth polished parietes, and a very narrow capacity. Hence it follows that in young girls, however narrow the orifice may appear, we may expect every thing from its dilatability; but in adults we must rely less upon this, and make use of a speculum that is but a little larger than the apparent capacity of the orifice; and, finally, in old people, we must be more reserved in the employment of this instrument, and proceed slowly and cautiously, to avoid lacerations, which would cicatrise but with difficulty, and have recourse to very small speculums; in addition to this, I have sometimes been obliged to prepare the parts for eight or ten days, by gradually dilating them with the assistance of a sponge prepared for the purpose.

It is especially the external labia that contribute in producing the enlargement of the orifice, also to the passage of the vagina itself, as we see in parturition, when the head of the fœtus presents itself at the vulva, it must, therefore, yield in the same manner when any voluminous body is introduced into the vagina, as when extracted from it. The assistant, then, who is intrusted with the separation of the great labia at the time the speculum is introduced, must allow them to dilate as soon as the introduction be commenced, without which there would be excessive pain, and the vagina

would be deprived of the power of dilating itself, consequently giving a much less free passage to the instrument.

Hence, it is not difficult for you to understand this manual operation. The woman must be laid across the bed, and her sciatic tuberosities placed on a level with the edge of the bed; the feet also must be supported by two chairs, the thighs sufficiently separated to allow the surgeon to place himself between them; the head supported by a pillow, and another must be placed under the pelvis, in order to prevent it from sinking below the level of the edge of the bed, securing to the trunk an horizontal position; the instrument, too, must be oiled and warmed. If it be in winter, the metallic cold would act unfavourably upon the parts, in causing a contraction of the vagina, and even produce more serious consequences. I have seen cases in which, only from the action of the cold, the introduction of the speculum offering otherwise no contra-indication or difficulty, brought on severe colic, and sometimes even produced all the signs of severe peritonitis. We, however, must previously examine to ascertain the situation of the uterine neck, and we must seek for it in a precise manner. Without this previous examination, we run the risk of directing the instrument in a wrong direction, and afterwards we shall be obliged, in order to find the neck, to have recourse to unnecessary movements, directed on the uterus, which would tend to irritate this organ. Besides, we ascertain by this examination, for the most part, the alterations of the neck, and particularly its dimensions, seeing at once whether it is a proper case for its introduction.

With the left hand you must separate the hairs and labia, with the right take the speculum, embracing with the index and middle finger the concavity of its handle; place the thumb on the instrument at its insertion, and thus present it to the vagina, with the handle directed towards the *mons Veneris*; and to prevent any obstacle arising, the operation must be performed gradually; should the fourchette be extended from before backwards, it is necessary to avoid all pressure on the perineum, so as to prevent transverse fractions, which would still further stretch this membrane; but it would be advisable to draw the perineum backwards, so as to make the centre of the instrument correspond to the centre of the vagina, and direct it with a line, which would go from the centre of the vaginal orifice to the inferior extremity of the cervix; and thus, having penetrated about an inch, we must give to the instrument a slight movement, which would bring it in the direction of the sacro-vertebral angle.

As the speculum advances the woman makes involuntary efforts; the vagina resists, contracts on the speculum, and presents at the extremity of it a kind of reddish ring with an opening in the centre, the circumference of which is formed by the contracted walls of

the vagina. Thus the whole extent of the parietes of this canal present themselves in a perpendicular direction to the eye of the operator, in proportion as the speculum, penetrating, unfolds them. I have stated that this rounded fold, or ring, presents in the centre of it an orifice;—the same thing takes place when the neck itself occupies the centre of the vagina, but should it incline to the one side or the other, we find the orifice in general follows the same direction, and comes near the circumference of this rounded fold; so that the greatest section of the vagina is opposite to the side to which the neck deviates. This particularity might indicate to a certain extent, for want of previous exploration, what is the direction of the uterine neck. This fold of the vagina, bearing some resemblance to it, might lead into error; but the neck does not present rugæ, as does the vagina, and its colour also is not the same.

In case of inflammation the neck is browner than the vagina; but in the healthy state on the contrary,—the mucous membrane of the vagina is pallid, and that of the neck still more so. In order to dissipate all kind of doubt, it is sufficient to press back gently the part which presents itself with a small piece of wood having a rounded extremity; if it be the vagina, it suffers itself to be repulsed by the slightest effort. Lastly, when we perceive the uterine neck, we must embrace it with the extremity of the speculum; but sometimes the neck is inclined backwards to such a degree, that it is impossible to see it. In this case it is necessary to withdraw the speculum about an inch, and raise its handle upwards and forwards, in order to direct its other extremity between the posterior wall of the vagina and the neck, in such a manner as to raise the latter, and expose its posterior surface to the internal orifice of the speculum. Thus, when the neck is too voluminous to be perceived at once in its whole extent, we may turn its extremity to one side or to the other, in order to expose successively the whole of its surfaces, and for the explanation of its whole extent it is necessary to direct the instrument in different directions. Nevertheless, these manœuvres require the existence of a complete state of insensibility of the neck, otherwise they could not be performed without danger.

When the speculum is conveniently applied, we can fix it in this situation still more by gentle pressure, and afterwards introduce into its anterior a small camel's hair pencil to cleanse the parts. The neck, even in its healthy state, is almost always lubricated with mucus, more or less thick, which would conceal the small ulcerations. Sometimes its softened, and hypertrophied labia, in exact opposition one with the other, conceal ulcerations situated at their internal surface: in these cases we must raise, with a female catheter, or blunt-pointed probe, the anterior lip; this is generally sufficient to discover

ulcerations, or even small tubercles, situated on the inside of the neck, and which are nothing more than vasculo-cellular polypi.

In order to make all these researches, if we make use of natural light, the patient must be seated opposite the window, and the operator must place himself a little to the right, to allow the rays of light to fall on the bottom of the instrument; if not, an assistant, placed on the left, illuminates with a candle every part of the vagina, in proportion as he advances.

Speculums, also, having two or more branches, are used, and must have their handles rather long to facilitate the opening of the branches. Some are closed; these present less bulk, and their introduction has been thought much easier, and their employment preferable in all cases; but I cannot coincide with this opinion: their introduction is easy no doubt; but the separation of the branches dilates the vagina, without allowing the external labia to concur in its enlargement, and hence arise those dragging pains of which I have previously spoken. Besides this, separation leaves an interval more or less extensive between the two branches, into which the vaginal walls protrude, and obstruct the sight, unless the dilatation be carried to an enormous extent. Lastly; in spite of all precautions, and the most consummate practice, it frequently happens, that we pinch the mucous membrane, and cause pain that might be avoided, by withdrawing the instrument open: this manœuvre, however, is not very easily performed. To conclude: I should recommend the employment of this kind of instrument only in cases where the superior part of the vagina requires immense dilatation, for example, in order to seize its neck for amputation; and, as regards the still more complicated form of speculums, their use I never have recourse to.

Some circumstances contra-indicate, or render more difficult, the employment of this instrument; the hymen exists altogether or in part, and then, of course, is an obstacle for its introduction, causing, if attempted, a very painful resistance, so much so, that unless the case be one of great urgency, we are obliged to desist altogether from its introduction. Nevertheless, should there be extensive disease of the internal parts of generation, it would be preferable to make a crucial incision in this membrane, and amputate the flaps, or else the introduction of the speculum, or the penis, might irritate and cause them to degenerate; consequently, in these cases, it is necessary then to make use of the smallest speculum. This is also necessary in old women, in consequence of the rigidity of the vagina. Membranous bands are sometimes formed in this canal. I once met with a case, in which, at about an inch from the uterine neck, was a circular membrane—a sort of diaphragm—having an orifice in its centre, and at once opposed all attempts of introduction either of the band or speculum.

The vagina is most frequently contracted in its superior third, and becomes conical, all the membranes contributing to its contraction. Above, the canal resumes its calibre, representing the appearance of an hour-glass. This disposition I have met with five or six times, and in one case I was obliged to cauterise the uterine neck, and to traverse this passage with a camel-hair pencil, filled with a solution of the acid of the proto-nitrate of mercury. Lastly; the vagina is sometimes the seat of small tumours, and which must be previously extirpated, if there is no chance of their allowing the instrument to glide over them.

I have already mentioned, in speaking of the touchée, cases in which there is such extreme sensibility of the vulva, that even the introduction of the finger will produce fits of hysteria; in such cases, it is very important to calm the irritation before the introduction of the speculum be attempted. An inflammation of these parts is a decisive objection to its use. The presence of deep ulcerations in the uterine neck or vagina will cause, easily, lacerations and serious hæmorrhages. I have witnessed a case of this kind, when the introduction of the speculum at an improper period produced extensive lacerations of the vagina, an unmanageable hæmorrhage, and the patient died two hours after the operation. When the neck is occupied with such voluminous vegetations that the speculum cannot embrace them, its employment is useless. Finally, it is important to defer the use of its application when there exists great hypertrophy of the uterus, accompanied with sub-inflammation. In short, since it is not possible to cauterise or to treat locally the superficial excoriations and ulcerations unless the tumefaction has nearly abated, the use of the speculum would be useless, and attended with some inconvenience.

CONTRIBUTIONS ON MIDWIFERY,

BY THOMAS RADFORD,

Surgeon-Extraordinary to the Manchester Lying-In Hospital, &c., &c.

NO. 1.

Case of Protracted Labour from Malposition of the Fœtal Head at the Superior Aperture of the Pelvis, with Descent of the Funis; with Observations.

ABOUT five o'clock in the morning, September 13, 1825, I was requested to visit Mrs. Carpenter, who was represented to be in severe labour of her second child. Mrs. Buckley, the midwife, informed me that she was called to this patient at eight o'clock the preceding night, and in consequence of not being able to ascertain the presentation, she ruptured the membranes. In the course of a short time, she was again examined, per vaginam, but a syet

no part of the child was accessible to the finger, but she found the funis protruding very considerably through the os uteri. After hearing this statement, I proceeded to investigate the real nature of the case. I found the os uteri dilated to about the size of half a crown, and situated very high, and very much backwards; it was also extremely rigid, and projected into the vagina. The head was so distant as to be with very great difficulty touched; so that it was impossible at this period to ascertain its exact relative position to the pelvis. The funis was very considerably prolapsed, and pulsated very strongly. The pains were very feeble, and the intervals between them long.

The os uteri being so rigid, a temporising practice was recommended; the funis was passed into the vagina, and retained by means of a napkin applied externally and a T bandage. The operation of version, or an attempt made to carry the funis upwards into the uterus, in order to save the child, would prove equally unsuccessful; whilst the forcible dilatation of the os uteri, and the unwarrantable introduction of the hand into the contracted uterus, the liquor amnii having been discharged eight hours, would have been a most formidable and dangerous operation.

At noon the funis had ceased to pulsate, but in other respects no great change was observed,—indeed, the descent of the head was so slow, that an advance was scarcely to be perceived the next day at 11 o'clock, A.M. In the afternoon of this day the pains became stronger, so that now the os uteri was rendered tense during their continuance, from the pressure produced upon it by the head. At this time the head lay over the superior aperture of the pelvis, and I was able, for the first time, to ascertain its precise relative situation to the pelvis. It was found entering in a very unfavourable position; the posterior fontanelle was placed behind and above the symphysis pubis, the sagittal suture in a direction from this point backwards to the promontory of the sacrum. The left parietal bone was more accessible to the touch than its fellow, in consequence of a slight obliquity of the head. The edge of this bone was very considerably raised, and offered through the os uteri a sharp edge, not unlike an ivory paper-folder. This change fully proves the great pressure sustained by the head in its

long diameter. During every pain the os uteri was most violently stretched upon this ridge; so much so, as to make the writer dread its laceration.

The difficulties produced by malpositions of the foetal head are fully appreciated by obstetricians. In none is the influence upon labour, for this want of relative adaptation, more conspicuous than in the case under consideration. The head enters the brim of the pelvis with its long diameter, which measures from four inches and a half to four inches and three-quarters, parallel to the short one of this cavity, which does not usually measure more than from three inches and half to four inches. It appears quite evident then from this statement, that a long time must elapse, and a considerable change in the figure of the cranium must take place, an alteration which is frequently fatal to the child, before it can get into the pelvis. In the present case the perforator was used; and as the child had been dead for some hours, and the time was at hand when some decided steps must be taken to protect the mother from danger, no compunction was felt in having recourse to this destructive instrument. As soon as an opening was made into the cranium, the brain was forcibly discharged through it, in consequence of its being so completely destroyed by the pressure it had previously sustained. Notwithstanding this, considerable time elapsed before the head passed through the os extertum. This delay, doubtless, was caused by the position of the base of the cranium, which is an incompressible part, and consequently it is not influenced in any material degree by perforation. The ancients regarded this position of the foetal head as the most frequent and the most natural; but this opinion, as experience has proved, is entirely untrue; it cannot be doubted they judged this to be the case, from what they occasionally observed in the situation of the head, when it emerges from the inferior aperture of the pelvis.

Baudelocque, Gardien, Dubois, Flamant, Dewees, Desormeaux, Velpeau, James, and Madame Boivin, admit this variety of labour into their classification; but these writers consider that it is of rare occurrence. Naegele, Maygrier, Capuron, Duges, Dr. Burns, Dr. Campbell, and Dr. Rigby, deny in toto the possibility of its happening, which opinion the case now related, as also those of Dr.

Dewees and Madame Boivin, entirely disprove. Notwithstanding, my opinion is, that this position of the foetal head, at the brim of the pelvis, does occasionally happen; yet I must in some measure qualify this statement, by remarking, that I consider it to be the result of an undue interference on the part of the obstetrician at the commencement of labour. To the same unjustifiable conduct may be attributed the prolapsion of the funis, which is so frequently fatal to the child. When uterine pains take place, and no presentation can be felt, we have grounds for suspecting a preternatural position of the child; although this is presumptive, it is not positive evidence of such being the case, and does not warrant the practitioner to make any interference. It sometimes happens that this remote situation of the presenting part of the child depends upon the condition of the cervix uteri, this part not being obliterated or fully developed; or, in other words, the full period of gestation not being completed.

Previous to the commencement of natural labour, and subsequent to the complete development of the cervix uteri, the head of the child falls down upon this extended portion of the organ; and, as a next step in the process of labour, the uterus, and its contents also, sink down, so as to be supported by the margin of the superior aperture. Before these changes take place, the presenting part of the child is with great difficulty discovered, if the examination is made through the os uteri; but if the finger is applied to the cervix, behind the symphysis pubis, it is much more readily felt.

In many instances also, where the liquor amnii exists in large quantity, the presenting part will be obscurely felt, as it so readily recedes before the touch even when only slight pressure is made. The practice of rupturing the membranes, in all the cases now mentioned, in order to ascertain the presentation, is universally to be condemned, as highly detrimental to the welfare of both the mother and the child. When the head of the child is not in contact with the lower portion of the uterus at the time the liquor amnii is suddenly discharged, there is great danger of the funis falling down before the presenting part, and passing though the os uteri; the risk of such an occurrence is much greater if it happens that the cord is of an unusual length; this was the state of the cord in the case just related.

In breech presentations, there is a greater chance of prolapsion taking place, if the obstetrician adopts the practice which I have just been animadverting upon. If the membranes are ruptured before the uterus is prepared for action, the head will rarely enter the pelvis favourably; for previous to the sinking of the uterus and its contents, into the superior aperture of the pelvis, the child is easily moveable in the waters; this floating of the child may be readily ascertained, when it becomes necessary to make an examination per vaginam, before the completion of pregnancy. But when the uterus has undergone the preliminary changes, preparatory to active labour, the head of the child may be felt through the substance of the uterus, as a globular body, presenting considerable resistance to the finger. At this period it assumes its final position, in relation to the pelvis. These preparatory steps of adaptation are beautifully illustrated in the graphic delineations of Hunter and Smellie. When the membranes are ruptured prematurely, the head sinks down, as also the body of the child, embraced by the contracting uterus, and it is then prevented entering the pelvis in a favourable manner. From such interference the child generally falls a sacrifice, and all the evils of protracted labour are produced upon the mother.

We come now to speak of the treatment of those labours, in which the head is placed with its long diameter parallel with the short one of the pelvis, as happened in the case now detailed. The means which have been recommended are rectification, turning, and perforation. The operation of rectifying the position of the head must never be attempted if the os uteri is rigid and undilated. Those measures, which have a tendency to relax the soft parts, and protect the adjacent organs from injury, must be adopted. Bleeding, carried to the extent that the case demands, or the powers of the constitution admit, emollient enemata, the catheter, and the recumbent position must be prescribed. Two methods of operating are to be considered; one by the use of the hand alone, the other by the aid of the long forceps. If the first method be adopted, the head must be seized in such a manner that the thumb be placed on the posterior edge of the parietal bone, close upon the lambdoidal suture, whilst the fingers are to be

fixed upon the anterior edge of the parietal bone, or upon the coronal suture, of the opposite side of the cranium. Then, in the absence of the pains, the head must be slightly raised, and turned by a double action of the thumb and fingers, so as to place it in the oblique diameter of the brim of the pelvis.

The bulk of the foetal head offers a great obstacle to any attempt made to change its position by the hand alone. The difficulties are increased by the contracted uterus after the escape of the liquor amnii. These circumstances induce me to give a preference to the second method mentioned, or the application of the long forceps. The blades of these instruments must be placed on the sides of the pelvis, and over the lateral parts of the head. The first object must be, slightly to raise the head; afterwards a very limited rotatory movement must be made, only sufficient to place the face opposite to the sacro-iliac symphysis. When this is effected, the instrument must be withdrawn. If the energy of the uterus is impaired, then such means must be adopted as are known to excite the contractions of this organ, friction, secale cornutum, &c. If these means fail, the forceps must be re-applied over the face and occiput, and the delivery finished in the usual manner. The perforator must be used, if the child is dead. This is ascertained by the funis being prolapsed, and by the sensations of the woman.

NOTICES OF WORKS ON THE PRACTICE OF PHYSIC, SURGERY, PATHOLOGY, AND PHYSIOLOGY, RECENTLY PUBLISHED IN GERMANY.

From the Dublin Journal of Medical and Chemical Science, Jan. 1834.

PROFESSOR GRAVES has enriched the pages of our contemporary by translations from recent German works, and few in this empire are so well acquainted with foreign medical literature. His important clinical lectures in our pages have elicited the highest praise in every part of the empire.

He informs us that one of the most interesting scientific periodicals in Germany is a weekly medical newspaper, published at Berlin, and edited by Dr. Hecker. All the hospital physicians and surgeons of the capital are contributors, and the work is also supported by provincial practitioners. In the number for

Jan. 30, 1833, Dr. Kluge has published some very valuable remarks.

On Iodine in checking Mercurial Salivation.

This writer states that Professor Knod Von Helmenstreitt, in Aschaffenburg, was the first who recommended iodine in mercurial salivation.—*Hufeland's Journ.*, May, 1832. He gave it in seventeen cases, twelve of which were women, and five men. The following is the prescription:—iodine 5 grains, spirits of wine 2 drachms, cinnamon-water, and half an ounce of syrup. The dose—a tablespoonful four times a day. The quantity of iodine was increased in some cases to eight grains daily.

Strychnine causing Salivation.

A patient in the Meath Hospital and County of Dublin Infirmary, under the care of Dr. Graves, labouring under painter's colic, after appropriate treatment, took one-twelfth of a grain of strychnine three times a day. When he had taken six doses he was salivated,—he had never taken a grain of mercury in his life.

We have given strychnine in such doses to a great number of patients at St. John's Hospital and Dispensary, as mentioned at a late meeting of the Medico-Botanical Society, and have never seen ptialism induced; neither has it been noticed by any of our colleagues.

Iodine in Strictures of the Urethra.

Dr. Trüsted, in the Berlin medical newspaper, has related a case of stricture of the urethra, enlargement of the prostate gland and testicle, with fistula in perineo, in which he ordered five drops of tincture of iodine three times a day, and a small portion of the ointment of the hydriodate of potass to be rubbed into the swollen parts morning and evening. The swelling of the prostate began to yield and diminish very considerably in eight weeks. Bougies were employed and gradually increased in size.

The treatment of this case commenced June 25th, 1832, and the patient left the hospital nearly quite cured Sept. 11th.

The narrator describes two other very obstinate cases of strictures relieved by the internal and external use of iodine with bougies.

Dr. Ryan proposed to use iodine in strictures of the urethra, and enlargement of the prostate gland, at the Medical and Medico-Botanical

Societies in 1832. He employed Mr. Gray's surgical instrument-maker, Castle-street, Leicester-square, to make him a wooden syringe for the purpose of injecting the ioduretted solution, proposed by Leydel, into the bladder and rectum in prostatic enlargement. He also requested his friend and colleague, Mr. Crump, to ascertain the influence of iodine, on the various kinds of bougies and metals, so as to ascertain the feasibility of applying it to strictures of the urethra. Mr. Crump informed him that iodine had scarcely any influence, at an ordinary temperature, on metallic bougies, and he, Dr. Ryan, has smeared bougies with the ointment of iodine with the best effects. He employed iodine, both internally and externally, in enlargement of the prostate, in a case at St. John's Hospital, which was known to Dr. Negri, Mr. Jenkins, and Mr. Nettlefold, with great benefit.

When the solution was injected into the rectum, the man was desired to take repose by lying on the anterior surface of the body; and the fluid was thrown into the bladder, as there was reason to suppose that the enlarged prostate projected into it, as minutely described by Mr. Brodie in his Clinical Lectures on Diseases of the Urinary Organs.

Corrosive Sublimate Baths in Chronic Rheumatism.

Dr. Ebel, in the paper already quoted, employed a bath composed of half an ounce, and finally an ounce, of the oxy muriate of mercury, with a sufficient quantity of water. The temperature at 94° or 95° Fah., and sweating was produced.

Birth of an Infant after the death of the Mother.

Dr. Trüsted relates a case, in which, an hour after death, a noise was heard, and an infant found between the limbs of the mother.

SURGEONS' HALL.

There having been submitted to the Royal College of Surgeons of Edinburgh, an authenticated copy of "Regulations for granting Medical Degrees, by the Senatus Academicus of the University of St. Andrew's," of date 9th December, 1833, it was resolved:—

1st. That the College experience much surprise in learning that an arrangement has

been entered into between the University of St. Andrew's and certain members of their own body, engaged in teaching different branches of medical science, in Edinburgh, for conferring, in the name of that University, degrees in surgery as well as in medicine.

2nd. That the College cannot but regard this novel assumption, on the part of the University of St. Andrew's, of a right to confer degrees in surgery, though not possessing in their own body a single professor in that branch of science, as being wholly uncalled for by any considerations of public expediency or utility, as a violation of the rights and privileges of this College, and as calculated, in as far as a smaller extent of education is demanded of candidates for that degree, than for the diploma of the College, to impede the exertions which this College have for many years been making, to raise the qualifications of those who receive their licence.

3rd. That in issuing at the present time a new code of regulations for conferring degrees in medicine and surgery, the *Senatus Academicus* of the University of St. Andrew's appear to have altogether overlooked the opinion so decidedly expressed by the late royal commissioners for visiting the Universities and Colleges of Scotland, viz.:—That the possession of this privilege by universities, circumstanced as theirs is, is “inconsistent with sound principle; and that the exercise of it, while it is directly opposed to the interest of the public, can be productive neither of credit nor legitimate benefit to those establishments.”

4th. That the College, independently of the doubts they entertain as to the right of a University to delegate any part of its duties or privileges to persons unconnected with it, cannot but consider it as an unheard of and unwarrantable aggression in one university, to establish an examining board, chiefly constituted of persons residing at the seat of another, and to appoint to that board teachers necessarily engaged in rival competition with the professors of their sister institution.

5th. That the College cannot overlook the coincidence in time between the promulgation of this new code of regulations by the University of St. Andrew's, and the announcement of certain extension of the course of study required by the University of Edinburgh

from candidates for its medical degree; nor fail to perceive, in this instance, a practical exemplification of the difficulty which (in the want of any general system of medical legislation) must always attend the efforts of public boards, to extend and improve the education of those on whom they confer testimonials; viz. the possibility of the same titles and equal privileges being obtained from other boards on a smaller amount of qualifications.

6th. That the College feeling, as they necessarily do, a warm interest in the character of the University of Edinburgh, and in the respectability of its medical graduates, conceive themselves called on to express, upon the present occasion, the satisfaction they have derived from the progressive extension of the course of study prescribed by that University to candidates for its medical degree, so as to insure that its holders shall, in respect of education and acquirements, be worthy of the dignity, and of their connexion with the institution—measures that could not fail to be more agreeable to the College, from being so completely in unison with those which they have themselves pursued in framing regulations for candidates for their diploma.

7th. That it is to the College a source of much regret, that any members of their own body should have engaged in a scheme for conferring surgical degrees prejudicial to the rights, liberties, and privileges of the College, which, on admission into it, they bound themselves faithfully to maintain and defend—and which scheme, if it operate at all, must be injurious to those interests which they at the same time undertook to promote to the utmost of their power.

8th. That a dutiful and loyal address be presented to the King's Most Excellent Majesty, praying that, in the exercise of that power of superintendence over the Universities which the constitution has placed in the crown, he will be graciously pleased to interdict the University of St. Andrew's from all further proceedings in this matter, till the report, presented to his Majesty by the late Royal Commissioners for visiting the Universities and Colleges of Scotland, shall have been duly considered by his Majesty's advisers.

By order of the Royal College,

JOHN CAMPBELL, M.D., President.

Edinburgh, 4th Jan., 1834.

ROYAL COLLEGE OF SURGEONS, DUBLIN.

THE Royal College of Surgeons held a meeting yesterday to elect officers for the present year. The following were duly elected;—President, J. Kirby; Vice-President, A. Read.

Court of Censors.—James Kerrin, Thomas Ramley, Maurice Collis, William Tagert, Robert Adams, Ephraim McDowel.

Court of Assistants.—Abraham Colles, Robert Harrison, Abraham Palmer, Edward Hutton, James W. Cusack, J. O. Beirne, W. Corbet, W. Hargrave, B. McNamara, John Hart, Charles Benson, Andrew Ellis.

Midwifery Court of Examiners.—L. H. Halahan, Chairman; E. W. Whiteston, Deputy Chairman; Robert Shackleton, L. Armstrong, S. Cusack, J. Peebles, T. E. Beaty, H. H. Maunsell; J. W. Cusack, Secretary; R. Harrison, Assistant Secretary.

CLAIMS TO THE EMPLOYMENT OF DEPLETION IN FEVER.

BY THOMAS SUTTON, M.D., GREENWICH.

I OBSERVE in No. 97, page 636, of your Medical and Surgical Journal, that you attribute to “the scrutinising mind of Broussais, and the active mind of Clutterbuck” the introduction of the depleting and antiphlogistic treatment of fevers, by attention, as you state, to some locale; likewise the relief from that panic, which had occupied the minds of medical practitioners, respecting the proneness of all fevers to run into a putrid and typhoid state, to be owing to their exertions.

On this subject I beg to observe, that it is probable that I had treated one thousand patients in fever on the depleting and antiphlogistic plan, in reference to local affections observed by post mortem examinations, before the gentlemen you mention ever thought on the subject. In the year 1794, this plan was adopted by me in Holland; and such was my confidence in it, that when I was taken ill of fever, I requested to be bled, which was done by the late Mr. Johnson, then a surgeon to the forces. In 1797, this treatment was adopted at Ashford, in Kent, in a fever prevailing at that time among the troops of that garrison, consisting of four regiments of militia. The practice was afterwards followed up under my direction for three years in

Deal General Military Hospital, commencing in the year 1798, and the morbid appearances diligently noted.

An abridged account of this practice, with the satisfactory results, was published by me in 1805. I must further remark, that this treatment, pursued under the eyes, and with the knowledge of many medical men, both regimental surgeons and such as belonged to the General Hospital, could not fail to find its way to the public, and to be disseminated in various directions.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Monday, January 13th, 1834.

Professor BURNETT in the Chair.

Pessaries—Imperforation of the Vagina—Secale Cornutum in Amenorrhœa—Iodine in Pulmonary Consumption.

THE usual business having been transacted, and notice given that the paper on venereal sores, by Mr. H. Johnson, was unavoidably postponed,

Dr. Jewel exhibited to the Society a large box wood pessary, which had been extracted from the vagina of a woman aged 52, and which had remained in that situation for 15 years; extensive ulceration of the parts, and offensive discharge had been caused by its presence, and as it is of large size, being eleven inches and three quarters in circumference, considerable difficulty occurred in its removal.

Mr. Costello mentioned the case of a female in the country in whom there was obliteration of the vagina, which had existed for some months; at the time of the menstrual periods she had great pains, similar to those of labour, and there was a tumour in the situation of the rectum; about 12 months since the patient had been confined, and it was since that time that the vagina had become imperforate. A case somewhat similar, in which there was complete obliteration of the vagina, had occurred lately in Paris, in the practice of M. Amusat, who proceeded to tear through the obliterated parts with his finger; the whole of the operation was performed with the hand alone, and with perfect success; the lady, who was a German, shortly afterwards married a medical man. The gentleman, who was attending the case first alluded to, was doubtful

as regarded the treatment, and he should be glad to hear the opinion of Dr. Jewel, or any other member, as to the proper operation to be performed.

Dr. Jewel said it was not very unusual for the vagina to become obliterated after labour nor was it difficult to remedy it; he had seen cases in which there was great contraction, yet when labour came on, the vagina dilated, and the patients did well.

Mr. Greenwood suggested the dilator invented by Mr. Weiss, as an instrument likely to be of service where there was any opening, however small it might be.

Dr. Johnson thought that the slow use of caustic might effect a cure; he had no doubt that the tumour was a collection of the menstrual fluid, and he should not hesitate to use Weiss's dilator, for the purpose of seeing where the obstruction was situated, and then to puncture it with a trocar, and he did not think that there could be any possible danger attending such an operation.

Mr. Chinnock said he would not hesitate to treat such a case as one of imperforate vagina, and use the knife.

Mr. Beevor had met with three cases in which the use of the knife had proved fatal; peritoneal inflammation had supervened, and notwithstanding the use of the lancet, and other antiphlogistic remedies, speedy death took place.

Mr. Costello had attended in Paris a groom who died after the introduction of a bougie; the cellular membrane between the bladder and peritoneum was found in this instance to join in the inflammation with the peritoneum.

Dr. Johnson said although peritonitis might occur, he did not think that such a termination ought to influence our practice, since it was very rare. Ague was a more common consequence of the introduction of a bougie, and he had seen great alarm excited by it in the minds of young practitioners.

Mr. Walker recommended a trial of Mr. Stafford's instrument in the case mentioned by Mr. Costello; he had seen a case of stricture in a man, in which the smallest bougie could not even be passed, terminate favourably under the use of Mr. Stafford's instrument.

Dr. Johnson mentioned some instances in which intense periodical pains in the breast of the female, without obvious cause, had led to

an examination, when scirrhus of the uterus was found to exist.

Some farther discussion having taken place on this subject,

Mr. Chinnock spoke of the beneficial effects of secale cornutum in amenorrhœa; he had seen in two cases half drachm doses of this medicine prove of decided benefit.

Dr. Jewel had never used it in such cases, but in leucorrhœa he had found its administration successful.

Dr. Epps then called the attention of the Society to the sympathy which existed between the lungs and the uterus; in pulmonary consumption where the patient only expectorated frothy mucus, he had frequently observed that at the time of the menstrual period, if the discharge did not take place, pus was ejected from the lungs, and that when the discharge could be produced, great benefit ensued.

Dr. Johnson considered this connexion very remarkable; it was not unusual for hæmorrhage, to a considerable extent from the lungs, to take place on the suppression of the catamenia, but in such instances the same degree of alarm was not created as in hæmorrhage from different causes.

Dr. Jewel had seen violent symptoms of croup usually preceding the catamenial period.

Several remarks upon the treatment of pulmonary consumption were then made by different members, and different plans of treatment were recommended, amongst others sulphate of zinc, with excess of sulphuric acid, prussic acid, iodine, mist. cretæ comp., and small bleedings.

The time for discussion now having elapsed, the Society separated until next Saturday.

MEDICAL SOCIETY OF LONDON.

Monday, January 13, 1834.

MR. KINGDON in the Chair.

MR. ROBERTS related the case of a young gentleman, aged 24, whom he had attended for pains in the bowels, and tenderness, on pressure, in the left iliac region; pulse 110, hard and full; pain in the head, and cough; he was bled, and purgative medicines, followed by spermaceti mixture, were prescribed; the medicine operated freely, and the pain in the head left him, but there was still a slight degree of pain in the abdomen; leeches were applied, and on the following day the tenderness had disappeared. Six days after this

time he was seized with excruciating pains in the bowels, his pulse became small and frequent; the extremities cold; and the countenance denoted anxiety; he grew worse, vomiting came on, and, at the end of 30 hours from the attack, he expired. No traces of disease were found in the head, but the intestines were slightly agglutinated, and a quantity of pus was found in them; they were also found to be perforated in two places, and there were other ulcerations, without elevated margins, and abrasion of the mucous membrane. He had considered this as a case of typhus fever.

Mr. Headland did not think that the present case bore any resemblance to any of those cases, mentioned by Dr. Armstrong, as cases of typhus; he alluded to the fact, that peritoneal inflammation might occur without the existence of pain; modern pathologists were in the practice of terming any increased redness of parts as inflammation, although no inflammatory symptoms had manifested themselves.

Dr. Uwins said it mattered not whether they called this case one of typhus or not; it appeared to him, that the symptoms, terminating in a changed state of the viscera, had especial reference to the condition of the nervous system.

Mr. Roberts did not think that peritoneal inflammation had taken place, until after the perforations of the intestine; it is probable that a sudden escape of fecal matter into the abdomen might have caused the sudden collapse which took place.

Mr. Field thought the more acute symptoms might have existed previous to the period mentioned by Mr. Roberts, since the intestines were found in a state of adhesion.

Mr. Kingdon said, that he had been called to a child, which had died suddenly, and was supposed to have been poisoned, in consequence of its having been in a state of good health the day before; the intestines were found lying in one mass of lymph, and agglutinated together. The discussion upon this subject having dropped,

Mr. Dendy rose to call the attention of the Society to the great sympathy now existing in some patients in London between the stomach and head. He had, at the present time, two cases under his care, in which the cerebral excitement was very great; the patients were

merchants, and probably the great anxiety, attending that occupation, might have aggravated the symptoms; purgatives, such as blue pill and castor oil, had given temporary relief, but the slightest constipation caused the return of the pains. He should be glad to hear the opinion of any member respecting the propriety of treating the cerebral, or gastric symptoms, and the use of purgatives, or depleting remedies.

Dr. Uwins was disposed to attribute this prevalent complaint to the sudden barometrical changes, which had occurred within the last six weeks. In the Peckham Lunatic Establishment he had traced these barometrical changes as influencing lunatics; he had been foiled in the treatment in some cases, for there was just enough cerebral irritation going on to show that there was something wrong in the brain, but not sufficient to justify depleting measures. He had found even the application of leeches injurious, but he thought that purgatives, acting on the lower bowels, were most beneficial; in treating the symptoms of gastrodynia he had found a combination of purgatives and subnitrate of bismuth very successful; leeches to the epigastrium had given temporary relief, but afterwards appeared rather to have aggravated the complaint.

Dr. Whiting said, that he had seen several patients, with insanity, within the last six weeks; indeed at one time he had four under his care; he could not, however, say that he had found these cases connected with the stomachic symptoms, these latter would undoubtedly increase, or even cause cerebral disturbance, but probably distress and anxiety had more to do with the cases he alluded to: opium, used to a good large extent, had proved useful, but he found that if not given in sufficient doses it did more harm than good; this remedy had not however proved always successful, and probably in those cases, in which it was of service, the symptoms were caused by anxiety and want of sleep; from 60 to 80 drops of Battley's liquor opii sedativus had been the doses in which he had given this medicine, and he found that these large doses did not constipate, but rather tended to produce a contrary effect; a strict attention to the diet was also absolutely necessary, and he was surprised to hear that mentioned in so slight a way by speakers.

Mr. Clifton thought that abstraction of blood.

was calculated to do harm in such cases as Mr. Dendy's; the fact of attention to the stomach and bowels, relieving the head for a time, showed that the cerebral affection was only sympathetic. He thought a rigid attention to the stomach and bowels, by continued mild aperients, rather than drastic purgatives, most useful.

Dr. Uwins said, that he agreed with Dr. Whiting as to the propriety of administering opium, but he was accustomed to give it in much larger doses, even to the amount of from two to three grains of the powder; in the cases where opium could not be given, he had used the fox-glove with great benefit.

Mr. Moore related two cases, in one of which there was great excitement from want of sleep; pulse full; flushed countenance; confusion of manner; together with symptoms of dyspepsia; two grains of opium and three of calomel procured him several hours' sleep; digitalis and aloes were afterwards ordered him, and in a short time he was quite well. The other case was very similar, but the application of leeches to the temples was required here, by similar treatment to that of the other patient he did well.

Mr. Kingdon found that in treating the cases, where pain in the head and gastrodynia existed together, by giving ten grains of blue pill at night, and nothing else until the bowels had been opened several times, and then administering the decoction of aloes, he had been successful in several cases. Some years since he had opened several bodies with disease of the ileo-colic and colic portion of the intestines, and, from what he had seen, he felt certain, that drastic purgatives were more injurious than useful; and he, therefore, carefully abstained from their employment. He had used bismuth with extract of rhæi in a case of dyspepsia, combined with melancholia, with perfect success.

The further discussion of this subject was adjourned until next Monday, as the time had expired.

**THE HUMBLE PETITION OF THE
PRESIDENT, VICE - PRESIDENT,
AND FELLOWS OF THE MEDICAL
SOCIETY OF LONDON,**

SHeweth—That the Society to which your Petitioners belong has been established for a

period of sixty years, and consists of Physicians, Surgeons, and Apothecaries; who associate together for the promotion of medical science.

That your Petitioners have long experienced many and serious grievances affecting the various branches of the profession, and are anxious to submit the same to a Committee of your honourable House; and therefore implore that your honourable House will be pleased to institute an inquiry into the state of the Medical Profession, and into the Regulations of the different Colleges, Corporations, or Faculties, connected therewith; relying, with perfect confidence, that your honourable House will see the propriety of legislative interference, and will cause such enactments to be made as shall tend alike to the improvement of the profession, and the preservation of the public health; and your Petitioners will ever pray, &c.

MEDICAL COMMISSION IN FRANCE FOR REFORM.

THE Minister of Public Instruction, in Paris, has appointed a Medical Commission, consisting of MM. Andral, Dubois, Orfila, Freville, Pauset, Vincens, Lafond, Lodebat, and Donne, to draw up a project of law for the education and regulation of the practice of medicine and surgery.

We have informed our readers, some weeks since, that the Academy of Medicine unanimously agreed—"That all men practising any branch of the healing art should be Bachelors of Letters," a degree like our B.A., and then acquire the degrees of Doctors in Medicine and Surgery. The Officers of Health or General Practitioners, to be suppressed, the Doctors to supply their place by receiving small fees; the Apothecaries to be confined to preparing all remedies ordered in the Pharmacopœia, and compound prescriptions, and prevented from practising medicine. Empirics to be put down, quack medicines to become patent, and every obstetric practitioner, male or female, to have been duly educated.

There can be no doubt but the Medical Commission will draw up a project of a law to this effect.

THE
London Medical & Surgical Journal
Saturday, January 18, 1834.

PLAN OF MEDICAL REFORM.

WE are of opinion, after the amplest consideration, that the legislature would never consent to the annihilation of the medical Colleges in London, or of any of our Colleges; nor is it necessary, because one act or law could, without the slightest injury to either, compel every one who intended to practise medicine, surgery, and midwifery, to qualify before both, without interfering in the slightest degree with the interests of either or any. Are there not several Colleges at Oxford and Cambridge under the title of University of either place? And does not the public recognise at present, a faculty of medicine and surgery? Our sentiments on medical reform are, we believe, such as are least liable to objection. They are briefly alluded to in a former article. We should imitate the plan proposed by the faculty in France. The education, both general and medical, should be the same in all our Universities and medical schools. Every one about to commence the study of medicine, should have received a good education in classics, mathematics, and natural philosophy; and the courses of medical instruction should be the same in all our Universities and Medical Schools. Every medical practitioner should be a Doctor in Medicine and Surgery; should have learned practical pharmacy; and should study clinical medicine and surgery in an hospital, or dispensary for two years, previous to appearing before the respective Colleges of Physicians.

There should be scientific apothecaries; and the Companies of Apothecaries in London and Dublin ought not to be

scientific bodies and wholesale druggists together. There should be some persons to prepare medicines, and compound prescriptions accurately and scientifically.

Chemists and druggists should be confined to the sale of drugs by wholesale and retail; but not allowed to compound prescriptions or to practise medicine, as they now do without any kind of medical education; nor should they vend poisons indiscriminately. General practitioners should be entitled to fair remuneration for their visits, and ought not to supply medicines; but after a certain time, all students commencing attendance on lectures should be required to become doctors in medicine and surgery, with liberty to practise either branch of science.

The remuneration of doctors in medicine and surgery might be regulated by the profession or the legislature, as in France, and vary from five shillings to one, two, or five guineas, for each visit, according to the future eminance of the individual.

No person, male or female, should practise midwifery, unless properly instructed.

Quackery should be put down, and no apothecary allowed to vend patent medicines.

Certain penalties for the infringement of such act ought to be recoverable before a magistrate, as in France.

Every physician, surgeon, and apothecary, who distinguished himself by his writings, discoveries, or celebrity as a practitioner, should, after a certain age and a certain standing, be entitled to become a Fellow, Examiner, or Member of the Council in the respective Colleges of Physicians, Surgeons, and Companies of Apothecaries to which he belongs.

All professorships, lectureships, medical appointments to hospitals, dispen-

saries, parishes, workhouses, prisons, lunatic asylums, should be made by the Colleges of Physicians, Surgeons, and Companies of Apothecaries.

There should be one or more physicians, surgeons, and apothecaries, or assistant-apothecaries, to every such public charity, and each should be fairly remunerated for his services.

The fees of physicians should be made recoverable, like those of surgeons.

Medical ethics should be rigidly enforced.

This is only a part of the plan of Medical Reform about to be adopted in France; and we see no reason why it should not be adopted in this country. It equalises the education, and secures the best medical advice to every class of society.

We cannot agree with those who strenuously purpose to institute a new Faculty in England, Ireland, and Scotland. The association of the Colleges of Physicians and Surgeons in each country, by an Act of Parliament, under the title of "Faculty of Medicine and Surgery," would answer every reasonable and useful purpose. If the Apothecaries' Companies cease to be tradesmen, let them be associated; but should they decline to do so, (and the London Company intimated as much during the last session of Parliament,) then let the College of Physicians examine in pharmacy and the College of Surgeons in midwifery.

We repeat our firm conviction, that the Legislature will not sanction three new Faculties, but will modify those now in existence. Let it be remembered, that Government refused to establish an Obstetric Board: the feeling of respect for existing institutions is much too strong to admit of their destruction. This was the feeling of the Westminster Medical Society, though grossly and shamefully

misrepresented by the Medical Gazette; and we call upon the profession in every town throughout the United Kingdom to meet and petition Parliament for a reform, based on just, equitable, and honest principles, such as we have proposed.

MEDICAL REFORM.—UNIVERSITIES.

A strange harmonious inclination
Of all degrees to Reformation.

The more they stir, the more they're tangled.
Hudibras.

IN commenting, on some late occasions, upon the new schemes of Medical Education, which have been lately issued by some of the great manufacturers and dealers in medical degrees, we called the attention of our readers to the necessary consequence of this sudden interference. Some transactions of the past week lead us to renew the subject; we are now furnished with a practical illustration of the justice of our comments;—we can now exhibit a specimen, not merely of the gross inequalities of the fabric, which is offered to the public in the shape of medical practitioners, but also of the jealousies, which the trading principle engenders amongst the rival manufacturers. In truth, it requires no great degree of penetration to foresee these effects. Whilst the medical corporations are attempting, by the exercise of their separate powers, to introduce some amelioration in their systems of education; they still leave untouched—they actually tend to produce—that very diversity of system, which is one of the greatest anomalies and evils in our whole medical constitution.

Let us, for a moment, confine our attention to the Universities. It is unnecessary to inquire into the origin of these establishments, and of the privilege which they claim, of conferring medical de-

gress*. Suffice it to say, that the paltry University of St. Andrews claims and possesses as large a privilege of dubbing doctors as the great aristocratical establishments of Oxford or Cambridge, and that both the large and small have, in justice, an equal claim to this lucrative right, since neither have the slightest pretence to a medical school; whilst the Universities of Dublin and Edinburgh possess a complete establishment for medical tuition in the capitals of two great divisions of the United Kingdom.

Originally the first rudiments of the learned languages were taught in Universities. In that state of things it was not improper to require of students in physic, that they should have graduated in arts before the commencement of their medical studies. The English Universities still insist upon this preliminary, notwithstanding the altered course of education;—the University of Dublin pursues the same system: but the Scotch Universities have long since dispensed with the degree in arts, and consider a reasonable school education as a sufficient initiative to the study of medicine. From the excellence of the collegiate education in Dublin, which is obtainable at a very moderate expense by persons of all religious persuasions, there is nothing very unreasonable in requiring medical students for the degree of doctor, to pass at least a couple of years in the general university studies for the degree of arts, should the four years, at present requisite for that degree, be thought too large a sacrifice of time in the spring of life. But whether this arrangement is ad-

visable, or the Scotch are right in dispensing with any collegiate studies in general literature;—what justification can be urged for the system pursued at Oxford and Cambridge?

No person can presume to enter their sacred walls, unless under the banners of the thirty-nine articles, and at an expense of between two and three hundred a year. And then the orthodox monied believer is compelled to reside at the University for the greater part of four years, during which he is altogether precluded from all opportunities of studying his future profession. Were it not for the kindred exertions of the London College of Physicians, in giving university graduates a monopoly of its Fellowships, a Doctor of Medicine of Oxford or Cambridge would have been as great a curiosity as a Dodo.

Some few years ago medical degrees were sold at St. Andrew's; no very great quantity of the base coin got into circulation; the thing was too shameless: but what little did, generally escaped notice, and passed current with metal of a purer standard. The degrees at Oxford and Cambridge, which were mere matters of course to the graduates of these universities, and which differed, in that restriction only, from those of St. Andrew's, were never sought except as preliminaries to the honours of the College of Physicians.

Oxford and St. Andrew's have both been stirring in the field of Reform. However incongruous and inconsistent are the schemes of education, proposed by these bodies in their new-born zeal for Reform, they seem to us to have admitted some general principles as indisputable, which may be turned to considerable use hereafter, when the whole state of the profession shall be inquired into before a proper statu-

* Those who wish to read a brief but comprehensive history of the Universities, and of their system of education, will find the whole subject admirably treated in the *Wealth of Nations*, Book v., c. i., Art. II.

nal. It is a remarkable coincidence that both these Universities leave the student perfectly open to seek his medical education where he lists. The admission of this fundamental principle necessarily arises from their total want of medical schools. Whether, in fact, they should possess any control in the republic of medicine, is a point still to be decided.

In the outset we alluded to a recent transaction of some importance, in reference to the late reforms. There will be found in another page of this number a manifesto, issued by the College of Surgeons in Edinburgh, against the efforts of St. Andrew's to retrieve its character, and to induce applicants for a degree in surgery to visit its walls. The University had appointed some of the members of the College as co-examiners with its Professor; and these gentlemen, who have been censured by the College, have published a replication, which we shall insert in our next number. The College of Surgeons have resolved to address His Majesty on the subject. We fully agree with the College in considering the whole affair of Reform, as attempted at St. Andrew's and elsewhere, as "a practical exemplification of the difficulty which, IN THE ABSENCE OF ANY GREAT SYSTEM OF MEDICAL LEGISLATION, must always attend the effort of public boards to extend and improve the education of those on whom they confer testimonials, viz. the possibility of the same titles and equal privileges being obtained from other boards, on a smaller amount of qualification."

It is, by the by, a circumstance worth noting, that physicians, while they strenuously contend for the separate education and practice of physicians and surgeons, claim, at the same time, from the omnipotence of their University degrees, the right to practise surgery!

SURGEONS ENTITLED TO DISPENSE MEDICINES FOR DISEASES PURELY SURGICAL.

SIMPSON V. RALPH.

APPLICATION was made to the Court of Exchequer on Tuesday, to set aside a verdict claimed by a surgeon for medicine and attendance on a disease of the eye, palpitation of the heart, and cough, on the grounds that the plaintiff was a surgeon only, and not an apothecary, and had no right to compound medicines. Counsel for the plaintiff maintained that he had acted purely as a surgeon, and called some medical men to show that the complaints were surgical.

Baron Bayley did not see why the plaintiff should not be allowed to dispense such medicine as was incident to his practice as a surgeon. The mere fact of administering medicine did not make a man an apothecary, unless it was his chief business.—Rule refused.

French Medicine.

White Oxide of Antimony in Acute Inflammations of the Chest.

THIS medicine has been employed by Dr. Michel, of Semur, (Côte d'Or), with such remarkable success in several cases of peripneumonia; that for the inflammatory affections of the chest he considers it as a specific. Out of 15 cases, thus treated, one only died; this person, who was a bricklayer, and much addicted to drinking, had been labouring under a very severe attack of severe peripneumonia, five days before the antimony was administered; 30 grains were given to him on the first day, and on the second this dose was increased to 40; a rigorous diet was prescribed, and, under this plan of treatment, the symptoms diminished in intensity. From the ignorance of the attendants, however, the medicine was omitted, and hot wine substituted for it, and this so aggravated the disease, that on the succeeding day he died. Of the fourteen others, eight were men and six women, from 23 to 56 years of age: eight of them (three men and five women) had only one lung affected, the pleura participating in the inflammation only in a slight degree. The treatment of these cases

commenced on the third or fourth day, and consisted of the administration of from 15 to 40 grains of the white oxide daily, and a low diet for the first four or five days; the medicine was given with great regularity; and in the course of seven or eight days all the patients became convalescent. The six others had peripneumonia, accompanied by intense pleuritis; from eight to ten leeches were, in the first place, applied to the most painful part of the chest, and in each case with some amelioration; after which the oxide of antimony was immediately had recourse to.

The fact of the disappearance of the pain in peripneumonia after the evacuation of blood, is a common occurrence, but, in general, it manifests itself again, and requires a fresh application of leeches; in these cases the pain either did not return, or was very slight. These patients did not, however, become convalescent so rapidly as the preceding cases; but recovery took place more quickly than under the ordinary antiphlogistic plan of treatment. The malady re-appeared in one case after the cessation of the medicine, but on again resorting to it for two or three days, the unfavourable symptoms disappeared. Fifteen grains of this remedy were given during the course of twenty-four hours to a man who had been afflicted for the last day with wandering pains in the chest, cough, difficulty of respiration, sanguineous expectoration, and symptoms of fever. By the time he had taken fifteen grains his symptoms were much mitigated, and, by continuing the dose, gradually increasing its quantity, he rapidly got well.

Experiments upon the Communication and Origin of Vaccine Virus.

BY DR. FIARD.

Three opinions exist as to the origin of the vaccine virus. 1st. That of Jenner, who supposed that it proceeded from a malady in the horse, called *the Grease*, which was contagious, and gave to cows that form of complaint denominated *cow-pox*. 2nd. That of Dr. Robert of Marseilles, who thought that the vaccine virus was nothing less than the small-pox poison communicated to cows, and modified by the transition. 3rd. The opinion that this complaint is as natural to cows as the rot to sheep, the small-pox, measles, or scarlatina to man.

For the purpose of proving the truth of

these opinions, Dr. Fiard has made several experiments, of which the following is the result.

He inoculated, with the matter taken from the heel of a horse attacked with grease, four healthy cows; three punctures were made in each teat, but no satisfactory result ensued, for neither eruption nor pustule was caused. He afterwards inoculated four cows with matter taken from a person who had been suffering under confluent small-pox for eight days; the punctures made with this matter did not produce the slightest degree of inflammation. Seven cows were then very carefully inoculated with the matter of small-pox, taken at the seventh day from a young man aged 23. At the end of the fourth day, in three cows, the teats which were inoculated presented a slight red blush, but, by the 8th, this had entirely disappeared. In none of the other cows was there even this slight degree of inflammation produced.

After stating the result of these experiments, Dr. Fiard expresses, as his opinion, that the cow-pox is a malady peculiar to cows; that it is very rare in England, in these animals; and that, in France, there is no evidence to prove that it has ever been produced; but in that country cows are subject to a disease which very closely resemble cow-pox, and which has apparently led to the error.

French Hospital Reports.

HÔTEL DIEU.

Tubercles developed at the origin of the third, fifth, seventh, and eighth pairs of nerves; loss of hearing, of sight, and of smell; preservation of the taste and of the sensibility of the integuments of the face,

BY M. NELATON.

A YOUNG woman, *ætat* 21, was admitted into the Hôtel Dieu complaining of intense pain at the bottom of the head. The motionless state of her features, the eyes projecting and fixed, her inanimate attitude, and even her voice, all seemed to denote imbecility. She had suffered from pains in the head for six years, and from that time until now her sense of hearing had been gradually becoming less acute, and within the last three months she had completely lost her sense of smell; the sensibility of the skin was every where perfect, and the

voluntary motions were performed with their usual energy. At her first admission the voice was very weak, but after she had remained some time in the hospital it became completely lost. A probe, placed on the conjunctiva, did not provoke any signs of sensibility, although this membrane was evidently inflamed and dry, the lachrymal secretion being interrupted. A probe, introduced into the nasal fossæ, could touch any part of the membrane without the knowledge of the patient; ammonia, placed under the nostrils, did not appear at first to produce any effect, but after some minutes it excited efforts to cough. The gustatory faculty of the tongue was, on the contrary, preserved, for the patient recognised salt placed in the mouth, the general sensibility of this organ was also untouched.

The patient died after being in the hospital nearly two months.

Upon examination, the olfactory and optic nerves did not present any lesion in all their course; the pathetic nerve, external motor oculi of the left side, glosso-pharyngeal, and hypoglossal, appeared free from disease.

All the other cerebral nerves were at least three times the healthy size; small spheroidal tumours, from two to three lines in diameter, were developed in the interior of the nerves or were attached to their sides; some of these tumours were circumscribed in shape, and destitute of cysts, whilst others were of an irregular form; the internal structure of all of them was similar, being of a thick yellow consistency. The two common motor oculi nerves were placed upon a tumour of this kind, and they were found also in the nerves of the fifth pair on both sides, but at different distances from their origin; the external motor oculi of the left side contained one half a line in diameter. The nerves of the seventh pair were found to be altered in structure, from their origin to the bottom of the internal auditory canal.

Italian Hospital Reports.

HOPITAL DE MILAN.

Encysted Abscess of the Brain.

A SOLDIER was attacked at the age of 25, with inflammatory fever, accompanied by intense pains in the head, tumefaction of the left parotid gland, and insomnolency; these symptoms yielded to antiphlogistic treatment, but at the

time of his departure from the hospital he still had pain at the bottom of the left orbit, and tingling in the ear on the same side. Some days afterwards, the febrile symptoms returned, and a swelling was observed in the situation of the squamous portion of the temporal bone; leeches, bleeding, and a fortunate attack of epistaxis, arrested the symptoms, but still the pains in the head returned periodically, and with augmented violence; the tumour increased in size, and he became deaf. No remedies were of any avail, and in a short time he was seized with vomiting, his pulse became small and irregular, and he died.

Autopsy.—The sinuses of the brain were gorged with blood, the membranes and the substance of the brain were also injected, especially in the left hemisphere; the middle and lateral portions of the latter were much increased in volume, and did not present any traces of cerebral convolutions; there was an aperture in the dura mater corresponding to the opening in the left temporal bone; the right ventricle was diminished in size, and above it there was a cavity existing in the substance of the grey matter; the medullary substance in its neighbourhood was in a state of ramollissement and contained a cyst, as large as a hen's egg, filled with pus; this cyst had thick walls and a fibrous appearance; it exhibited in its interior the characters peculiar to inflammations of mucous membranes, and was a communication between it and the tumour situated upon the temporal bone.

Egyptian Hospital Reports.

HOPITAL D'ABOU-ZABEL.

Amputation of the Foot at the Tarso-Metatarsal Articulation.

BY CLOT BEY.

MAHOMET, æt. 25, was admitted for a wound of the foot produced by a wheel passing over it. The accident occurred twelve months previous to his admission, but he had continued his employment until that time. On examining the foot, it was found to be in a state of gangrene, and there was so great a loss of substance that cicatrisation became impossible. Disease of the bones had commenced, and his health was so much injured, that Clot Bey determined to perform partial disarticulation. Accordingly, with a long knife he made an incision through the integuments

covering the tarso-metatarsal articulation, where the wound terminated; he then plunged the point of the instrument between the articulation of the bones of the tarsus and those of the metatarsus, divided rapidly the integuments and tendons, and then, by turning his knife horizontally, made a sufficient flap beneath the bones to cover the wound. At the end of two months the patient was well, with the exception of a small abscess on the internal side of the foot; this abscess was opened and soon disappeared.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Hæmorrhoids.

We noticed in a former number some clinical remarks made by Mr. Brodie upon the case of Marshall, a patient in Fitzwilliam Ward, who was admitted under his care for piles. These (three in number) were tied, but the operation was not followed by that quick and immediate relief to pain and suffering which it usually affords the patient. He complained for some time afterwards of great pain in the part, and of a heavy bearing down whenever he went to stool, and he also passed some blood at the same time. His countenance was sharp and anxious; tongue clean; bowels open; pulse natural.

R. Confectionis Sennæ, ℥iss;

Sulphur Sublim. ℥iv., misce. Capiat coch. parv. bis in die.

Whilst examining this patient, a gentleman present asked Mr. Brodie whether he had used the balsam copaibæ in diseases and morbid affections of the rectum. Mr. Brodie answered in the affirmative, remarking that it was a very useful application, and acted in such cases as a stimulant to the parts, but that he did not consider it so useful a medicine in such cases as the confec. piperis nigri, which acted also as a stimulant, and when not taken by the mouth, might be introduced as a track or suppository into the rectum, when it became mixed with the fæces, and acted as a stimulant applied directly to the parts. The balsam copaibæ, Mr. Brodie remarked, was also a very good application in old obstinate gleet, when introduced on a bougie into the urethra. Mr. Brodie here alluded to a case of disease of the rectum which he had under his care, and which he believed to be carcinoma, and which he almost believed to be so still, and which had been materially benefited by the use of the balsam copaibæ and liquor potassæ combined together.

The patient complains of less pain, but had some blood come away with his stools a few days since, owing to the separation of one of the ligatures.

R. Confec. Piperis Nigri. Sumat quantitat. nucis moschat. ter in die.

Cont. Electuarium ut antea præscript.

These remedies were ordered to be continued for some time, till the after symptoms of the operation were completely checked.

On next visiting him he complained of great pain at each fecal evacuation, and said that the piles came down as much as ever. He was ordered to continue the use of the confect. piperis nig.

Mr. Brodie remarked that for one case of hæmorrhoids in hospital practice he met with twenty cases in private practice; and that when they occurred in hospital practice, they were more troublesome to manage, having generally lasted for a long time, and being complicated with disease of the rectum, from the hæmorrhoids having been neglected.

Under the use of the confec. piperis nigri, the man improved very much, and he was, therefore, made an out-patient, and ordered to continue the use of the confection.

Injuries to Cellular Membranes.

A man was admitted who had received a kick from a horse on the leg, which had injured the cellular membrane, and caused it to slough away through an ulcerated opening in the skin. Mr. Brodie remarked that the cellular membrane possessed a less degree of vitality than the skin, and that a blow or an injury which affected not the latter, might still affect the former; which would inflame, ulcerate, and slough away, as it had done in this case. If such cases were attended to in time, the skin over the part receiving the blow might be saved by being freely incised, thereby giving vent to the slough of cellular membrane beneath. The latter argument received an apt elucidation in a case to which Mr. Brodie's attention was soon afterwards directed, in which there was a large unhealthy sloughing ulcer of the leg, and the surrounding parts were very red and tumefied, from diseased cellular membrane beneath, and in which Mr. Brodie freely incised the surface in every direction.

Fractured Ribs—Injury of the Lungs.

A man was admitted labouring under such an accident. Bleeding, rest, bandaging, and the other usual remedies in such cases, were adopted with benefit. Mr. Brodie remarked that there were two ways in which ribs were said to be fractured; one in which the fracture occurred at the part immediately where the bone was struck where the ends of the ribs were driven in; and the other where the sternum was pressed in, and the ribs snapped like a bow, from being over bent. In this case the former of these accidents had occurred, and not merely the pleura pulmonalis, but the pulmonary structure of the lungs themselves had been broken into, for the man had spat up blood, which proved that the injury had not been a superficial one, for the blood-

vessels were situated very deeply. With respect to bandaging in such cases, it was formerly only employed where no emphysema existed, and Sir William Blizard was the first surgeon who employed it in cases of this nature, where emphysema did exist. There had been some emphysema in this case, and the man had borne the bandaging tolerably well, taking all the circumstance of the case into consideration.

Gout.

This man, gentlemen, has got gout; he has had it in the foot, and now he has it in the elbow, and it has been arrested by a good dose of colchicum. He is a post-boy: now that is not a mode of life particularly predisposing to gout. He had, I believe, fracture of the leg some time since, and he had gout after that. Now you will frequently find, that, in persons predisposed to gout, an attack will come on after an accident, such as this; and I have known it to occur after an operation.

Condylomata.

Condylomata frequently are caused by dirt. There may be a slight eruption about the anus, the acrid discharge from which may irritate the parts, and induce condylomata. A woman with fluor albus may have condylomata, —any discharge or dirt will cause it. The case which called forth these remarks was cured by the unguent. hydrarg. præcip. alb.

Fracture of the Cervix Femoris.

There are at present three or four cases of this nature in the hospital, under the care of Messrs. Keate and Brodie. Rest, in the recumbent position, with splints or padding to the part, as the cases may seem to require, are the general methods of treatment adopted in such cases, with attention to the general state of the patient's health. There is nothing particularly worthy of comment or observation in either of them; and we shall, therefore, take the opportunity of appending some clinical observations on such cases, made on a former occasion by Mr. Brodie.

The true fracture of the cervix femoris is situated in that part of the bone between the head and body, or long shaft of the bone, and which is enclosed or surrounded by the capsular ligament of the joint. There are many accidents of the femur which may be confounded with this; as, for instance, where the fracture of the bone is situated between the trochanter and shaft of the bone, and where the neck of the bone is in consequence drawn up, or again, where the fracture is situated at the juncture of the little trochanter with the neck of the bone, the case may be mistaken. The present observations, however, which I shall make, allude to fracture of the neck of the bone within the capsular ligament.

Fracture of the neck of the femur may be distinguished from dislocation of the bone upwards and outwards on the dorsum of the ilium, with which it is sometimes confounded,

by the following diagnostic marks:—If there is dislocation, you will find a great projection of the trochanter, which is less in fracture of the neck of the bone; in fracture there is no shortening; in dislocation there is shortening of the limb from the beginning; in dislocation the toes are turned inwards, in fracture they are turned outwards,—it is very rare to find them turned inwards in such cases; in fracture of the neck of the bone you can rotate the limb, in dislocation you cannot; in dislocation the knee and thigh are thrown forwards to the opposite side, in fracture of the neck they are not; in fracture there is great pain felt on the upper and inner parts of the thigh if it be moved; the great trochanter also is in its natural situation; sometimes the limb is shortened and sometimes not; if it be shortened, the great trochanter appears less prominent; if not shortened, the broken ends of the bone are in apposition, and the great trochanter is consequently in its proper situation. Sometimes you may feel the ends of the bones grating against one another; if you feel this grating you may be assured that there is fracture; if the limb be shortened rotation will not produce grating; but if it be not shortened and rotated the grating will be felt; or even if shortened this will be also felt if the limb be rotated at the same time that it is extended, by which means the broken surfaces will be brought nearer together; in these persons you will feel on rotation that the great trochanter revolves in a smaller arc of a circle. You will find no extravasation in fracture of the neck of the femur; it generally occurs in elderly persons, and but seldom in the young; in old age the neck of the bone becomes brittle, and a slight blow will fracture it; the shaft of the bone is less so, and therefore this symptom will guide you. The diagnosis in such cases should not be made from one symptom but from many; they must be all combined to enable you to judge of the true nature of the accident. The injury is at first frequently overlooked, owing mainly, I believe, to the circumstance, that there is no shortening at first immediately after the accident. Morgagni names this circumstance; and I am now quite sure that in many cases you cannot perceive any apparent shortening at first, and sometimes not until three weeks after the accident. The edges of the broken bone dovetail together, and the capsular ligament supports them. If there be no shortening, there will be great pain when the foot is put to the ground, the limb will give way, and the patient will be lamed. I knew of one case, however, which was an exception to this rule: the patient could put his foot to the ground; there was no shortening, and yet there was fracture of the neck of the bone.

These, then, are the circumstances which should guide you in your diagnosis in such cases: the age of the patient being advanced; the blow slight; the toes turned outwards or forwards; pain on motion, felt at the upper

and inner surface of the groin; if the limb be shorter, and it be extended and rotated, grating will be felt; but the shortening may not take place till two or three weeks after the accident, and sometimes even later than this.

ROYAL COLLEGE OF SURGEONS.

Unrolling of the Mummy of Horsiesi.

ON Thursday last, an immense concourse of the profession and other scientific individuals attended at the theatre of the Royal College of Surgeons, to witness the interesting process of unrolling an Egyptian ecclesiastic, and stripping him of the cerements of a thousand years. We are not sufficiently versed in hieroglyphics to read the gentleman's name in the original, but it is said to be Horsiesi, and that he was the son of Naspihiniegori, and an incense-bearing priest in the Temple of Ammon, at Thebes.

Mr. Pettigrew, who conducted the process, entered into an elaborate and eloquent review of Egyptian hieroglyphics, and explained many parts of the adopted system of interpretation. The learned gentleman gave an interesting account of the process of embalming in the course of his labours of evolution. The rollers were stated to be of most extravagant length, and were applied with wonderful skill. Amulets, &c., were found on the chest, and an Egyptian idol was lodged between the thighs. The process occupied an hour and a half, when the learned gentleman was obliged to defer a very delicate part of the operation, in taking off the rollers near the skin, to a future day. The learned President, Mr. Guthrie, announced, that in the meantime the mummy will be exhibited in the Museum on Mondays, Wednesdays, and Fridays, for the inspection of members of the College, and others introduced by them; and that the Secretary will be directed to issue tickets of introduction to any scientific individual who is disposed to avail himself of the privilege.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, January 9th.

John Maurice Conway	Lynn Regis.
Alfred Cooper	{ Whetstone,
	{ Leicestersh.
Charles Cotton	Liverpool.
Robert Hunt	Hull.
George Frederick Knipe	Hereford.
Elias Thomas	Bristol.
John Watkins	Cardiff.

LITERARY INTELLIGENCE.

SHORTLY will be published, *Elements of Medical Police, or the Principles and Practice of Legislating for the Public Health*. By BISSET HAWKINS, M.D., Professor of Materia Medica in King's College.

BOOKS.

A Series of Anatomical Plates, with References and Physiological Comments illustrating the Structure of the different Parts of the Human Body. By JONES QUAIN, M.D., Professor of Anatomy and Physiology in the University of London. Parts V. IV. and VI.

Principles and Practice of Obstetric Medicine, &c., &c. By D. D. DAVIS, M.D. Professor of Midwifery in the London University. Parts XXVI. and XXVII. Taylor.

History of a Case of Epilepsy of Twenty Years' standing cured, with the Treatment and Remarks thereon. By JOHN EPPS, M.D., Lecturer on Materia Medica and Chemistry.

The Baltimore Medical and Surgical Journal and Review. Edited by G. GEDDINGS, M.D., Professor of Anatomy and Physiology in the University of Maryland. No. I., Oct., 1833, London, Rich, Red Lion-square.

The Parent's Dental Guide. By W. IMRIE, Surgeon Dentist. London, 1834. John Churchill.

CORRESPONDENTS.

A Surgeon at Reading.—The certificate system was very properly excluded at the Westminster Society; and the idea of dispensing with attendance on lectures is preposterous—"a tub to catch a whale." It is a very palatable doctrine to many students and apprentices, who imagine that they could acquire a proper knowledge of all the medical sciences without any instruction or assistance. Were self-taught candidates to apply for examination, not one in five hundred could succeed, and the time of the examiners would be wasted.

O. The consequence would be a prosecution for a misdemeanour; conviction, twelve months' imprisonment, at least, and eternal disgrace.

A Member of the Westminster Medical Society.—We shall withhold this letter until after the next meeting of the Committee.

The Gregorians.—They have had enough already.

E. M.—Many thanks for the communications, all of which will appear next week.

R. A. G.—If the author of the Defence of the Statutes of the University of Oxford, with regard to Medical Degrees, will attach his name to it, we shall publish it. Our readers would certainly wish to know, whether it is the composition of an Oxonian Graduate in Medicine.

Mr. Dermott.—We have received Mr. Dermott's letter; but we think the publication of it in its present shape would defeat his object, in which we heartily wish him success.

Dr. Ryan has removed his residence to No. 4, Great Queen-street, St. James's Park, Westminster.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publisher, 356, Strand, near King's College.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

Delivered at the University of London,

Session 1832—1833.

LECTURE LXXIII., DELIVERED MARCH 22, 1833.

GENTLEMEN,—One of the most common secondary symptoms is ulceration of the fauces, tonsils, and soft palate,—in other words, a *sore throat*. What has generally been considered as the most unequivocal specimen of syphilitic ulceration of the throat, is remarked to come on without much previous inflammation, to begin on the surface of the part affected, and to extend more and more deeply; so that, when situated on the tonsils, an appearance is produced, as if a portion of them had been scooped away. The sore has a sharp prominent margin, and its excavated surface is covered with yellow adhesive matter, that cannot readily be separated from it. It is not uncommonly believed, that a sore throat, corresponding to this description, is peculiar to true syphilis, or the scaly form of the venereal disease—that disease, all of whose symptoms are sometimes thought more particularly to require larger quantities of mercury for their cure, than other varieties of the venereal disease. On this point, however, I may observe, that the doctrine, to which allusion has here been made, is not so much insisted upon at the present day, as it was some years ago. In fact, this kind of sore throat has frequently been cured by sarsaparilla, as you may learn from the statements in Mr. Rose's valuable essay; and it sometimes follows sores, which have no kind of resemblance to chancre, with an indurated base and circumference. At the same time I am of opinion, that, whenever this kind of sore throat is accompanied by a scaly eruption, or by pain in the shafts of the long bones, or by true nodes, it will be more benefited by mercury than any other kind of medicine.

VOL. IV.

Besides this description of sore throat, gentlemen, you will see in practice superficial, but foul and wide-spreading ulcerations of the tonsils, velum pendulum palati, and upper portion of the pharynx,—extending, in short, over a great part of the surface of the throat, and accompanied by a considerable deal of pain, restlessness, and fever. On account of its appearance, it is frequently called the *ulcerous excoriation of the throat*. Mr. Carmichael thought he had traced it to be an effect of what he terms the *papular venereal disease*, or that which he conceived to arise from the *simple primary sore*, patches of excoriation on the prepuce, or gonorrhœa virulenta.

You will also be called upon to attend cases in which the ulcers of the throat have a truly phagadenic character, and are disposed, under improper treatment, to destroy the whole of the soft palate, and to extend their ravages to the pharynx, and even sometimes to the larynx, causing necrosis of its cartilages, and endangering life. You will also find in this form of sore throat, when the constitution is in an unfavourable state from the injudicious use of mercury, a tendency to the production of caries and necrosis in the bones of the palate, and even in the upper jaw-bone and the ossa spongiosa; but if the disease be properly treated, and the employment of too great a quantity of mercury be avoided, the patient will generally escape the serious mischief to which I have alluded. You should be careful not to confound common abscesses, and chronic scrofulous enlargement of the tonsils, with venereal affections of them.

One species of *iritis*, or *inflammation of the iris*, is an affection ranking as a secondary symptom of syphilis. After the appearance of disease of the skin, or sore throat, or, after the patient has suffered pains in the bones, you will find that the iris sometimes inflames. This affection may follow, or accompany, various kinds of syphilitic eruptions, and is usually attended with pains in the limbs and joints; but it is not necessary for me to dwell on this part of the subject at present, as I shall have to notice it again in a few days, when *syphilitic iritis* will be considered, with other diseases of the eye.

3 F

With regard to *venereal affections of the bones and joints*, if the swelling has come on suddenly, seems to be chiefly seated in the periosteum, and the pain is not remarkably aggravated at night, you may generally conclude that it is not a venereal affection. True syphilitic nodes are more indolent and sluggish in their progress, than the swellings to which I have now referred; and, though they become painful in time, they are not remarkably so at first. In true syphilitic nodes, too, the pain is always more severe at night than in the day. The swellings, most likely to be mistaken for venereal ones, are inflammations of the periosteum, and not of the bone itself, attended with pain in their very commencement, and even with redness of the skin; they arise suddenly, and frequently disappear in a short time, without the use of mercury. They are said, therefore, to have more of the inflammatory character about them, than usually belongs to venereal nodes. The best plan in these cases is to inquire into their history; in all suspected cases of syphilis, indeed, you should inquire into the other symptoms which may have previously existed, the order in which they have occurred, and any treatment that has been tried; and you must form your conclusion by connecting the present symptoms with all the others which you can ascertain to have previously existed, not omitting the consideration of what may have been done in the way of treatment before you are consulted.

There is one curious circumstance deserving your attention in relation to nodes, namely, that they are alleged to be rarely produced in syphilis, unless the patient has been using mercury. This is a curious fact; but it is so much the case, that Dr. Hennen, a man of considerable observation and great experience, affirms that he never saw more than two cases of nodes in patients who had not taken mercury. I know that some surgeons maintain that the fact is otherwise; but I believe, that there is a great deal of truth in Dr. Hennen's observation, and that you will rarely meet with patients who have nodes, unless they have been taking mercury. But here the question arises, how far the mercury is concerned in producing these nodes? In considering this question, you should recollect, that, though you do not see nodes in syphilitic affections, unless mercury has been given, yet in liver complaints, for which mercury is often given in considerable quantities, and for an immense length of time, there will never be any nodes produced. On the other hand, it is asserted, that, if no mercury be given in the treatment of syphilis, nodes will not be produced. It seems, then, as if the action of mercury, and the influence of the syphilis together, had a share in bringing on these osseous swellings. You will not, as I have said, see nodes arise in liver complaints, though great quantities of mercury be employed. The venereal disease, therefore, is certainly concerned in the production of nodes. At the same time, it seems

to me that we have sufficient evidence to show, that, unless mercury be given in some quantity or another, great or small, for the cure of that disease, nodes and other affections of the osseous system will rarely be excited. I entertain not the slightest doubt also, that there is some truth in the opinion, that caries and necrosis of the bones are not so much the consequence of the venereal disease itself, as of the baneful influence of mercury, when it is rapidly and unskilfully thrown into the system, at a period when the patient is exposing himself to the weather, not confining himself at home, and committing the most imprudent excesses in diet. I believe that, under such circumstances, an individual is far more likely to have his osseous system affected, than one who observes a more prudent regimen during a mercurial course; and it is my firm conviction, grounded on remarks which I have made in practice, that caries and necrosis of the bones of the nose would very rarely occur, if mercury were not given in immoderate quantities, and the patients took due care of themselves while taking that medicine.

Gentlemen, in the *treatment of the secondary symptoms of syphilis*, the same general rules and principles, respecting the use of mercury, are necessary to be attended to, as I explained to you in describing the treatment of the primary complaints. I may say, then, that mercury will generally expedite the cure of the secondary symptoms; but that, in some states of the constitution, even when true syphilitic affections are present, or when ulcers, which were originally of this nature, have assumed the phagedænic or sloughing character, and are accompanied by considerable inflammation, or much derangement of the health, mercury will prove the most pernicious medicine that can be employed. Mercury will also be improper where any extraordinary inflammation is present with the secondary sore. Mercury will not benefit the secondary symptoms of syphilis in many disordered states of the constitution. Then, gentlemen, I can assure you that you will never treat either the secondary symptoms, or any other forms of the venereal disease, with judgment and discrimination, unless you recollect various facts connected with this subject; and one of these is, that mercury will generally benefit not only the ordinary forms of the venereal disease, but many other complaints; it will cure not only syphilis, but many other diseases which resemble it, and many also which are totally different from it. You should likewise recollect, that many diseases, which are successfully treated with mercury, sarsaparilla, guaiacum, antimonials, mineral acids, &c., would generally get well of themselves in the end, if the constitution could bear the requisite struggle. And with respect to mercury, or any other powerful medicines, be it also remembered, that if they are not administered in such doses as totally to derange the whole economy, if only moderate quantities of them

are exhibited, they will not commonly prevent any disease from taking a favourable course, if it be so disposed. Such reflections will render the fact very intelligible, how, in forming an opinion of the nature of syphilis, and of the effects of mercury upon the disease, so much deception has frequently occurred. A patient takes mercury in moderation, and his disease gets well, and then the practitioner is confirmed in his idea, that the disease was venereal, and has yielded to the specific remedy. But it will be sufficient for you to recollect the facts I have specified, to be convinced, that mercury is by no means a test of the venereal character of a disease. With respect to the treatment of secondary symptoms generally, I may observe, that when mercury is given, it is preferable to give it in moderate doses. In particular instances it may be necessary to push the mercury beyond what may be denominated a mild mercurial course, but such examples are uncommon; at all events, they are not so numerous as they are supposed to have been in former times. As a general piece of advice, however, I recommend you to adhere to the maxim of not exciting a profuse and violent salivation.

When the cutaneous eruption consists of scaly copper-coloured blotches, presenting the character of either psoriasis or lepra, and not attended with much febrile disturbance of the system, and perhaps associated with that affection of the tonsils, which is sometimes thought to be the greatest test of true syphilitic ulceration in the throat, namely the deep excavated ulceration, frequently accompanied by pains in the shafts of the long bones; all surgeons of experience agree, that mercury should be prescribed, and the majority recommend it to be employed according to the principles I have explained to you, namely in moderate doses, and not so as to excite a profuse and violent salivation, or to bring on severe derangement of the health.

With respect to secondary symptoms generally, it has been noticed, and is believed by a great number of excellent surgeons, that when mercury is useful in this stage of syphilis, it shows its efficacy with even greater promptitude than in the first stage, or in the treatment of the primary sores and buboes; I mean to say, that mercury will frequently remove the secondary symptoms with greater rapidity, and a smaller quantity of the medicine will be sufficient.

Ulcers in the throat may be fumigated with the red sulphuret, or with the grey oxide of mercury, or they may be washed with a solution of the chloride of soda, with the black wash, or with gargles containing oxymercuric acid, or with any other detergent gargle; but those applications, which I have mentioned, seem to deserve your particular attention on account of their very frequent good effects. Secondary ulcers in other situations may also be fumigated with benefit, and either poulticed still they granulate, or dressed with various

applications, as with the watery solution of opium, or henbane, when they are painful, or with the black wash (which is so common an application to primary sores), or even with the yellow wash, consisting of lime water and oxymercurate of mercury; or, if they are of a more indolent character, you may dress them with the ointment of the nitrate of quicksilver, or with the red precipitate ointment.

When the eruption is papular, and has been preceded by a great deal of fever, and considerable disturbance of the system, and when such eruption ends in desquamations (for you will find the papular eruption will sometimes desquamate), then you may employ blood letting in the commencement, with the compound calomel pill and saline aperient medicines. The same practice should be pursued, if there be pain and swelling of the large joints, accompanied by a diffused redness, and swelling of the tonsils and glands of the neck. Here you may suspect, that some particular state of the constitution has had a share in thus modifying the disease; it has never yet been proved, that such modification is owing to a specific poison, though you know, it is Mr. Carmichael's suspicion, that it may depend on some other poison different from that of true syphilis; but this still remains a questionable point; and, at all events, the state of the constitution must have more or less share in modifying the symptoms. After continuing the treatment that I have mentioned for a time, it is to be changed for small doses of James's powder or antimonial powder and sarsaparilla. Mr. Carmichael, who is certainly a good practical surgeon in these cases, entirely disapproves of the use of mercury in the commencement of the treatment of what he terms the *papular form of the venereal disease*; he does not even give the compound calomel pill, which contains but a small quantity of mercury; in short, he expressly avoids administering mercury, till the eruption desquamates, and then he admits that such medicine in moderate doses will be superiorly useful. With respect to that form of itritis, which is met with in syphilis, mercury is highly necessary, and should be given freely, for reasons that will be explained in a subsequent lecture, in conjunction with bleeding and blistering.

When the secondary symptoms are associated with a *pustular eruption*, you should begin the treatment with alterative medicines, especially antimonials, or the compound calomel pill. These medicines should be followed up by the compound decoction of sarsaparilla, or bark and the nitric or sulphuric acid. What is called the *sulphurous bath*, is frequently highly beneficial in this form of the venereal disease; though you will not always have opportunities of procuring your patients the advantages of it. The nitro-muriatic acid bath, and bathing the skin with lotions of the sulphuret of potash, are also frequently serviceable. Mr. Carmichael does not give mercury in the pustular form of syphilis, unless the pustules change

into scaly blotches, which, he says, they will sometimes do; but he chiefly trusts to sarsaparilla and guaiacum, with small doses of James's powder, or of the compound powder of ipecacuanha.

When white apthous ulcers of the mouth accompany syphilis, they may be touched with a solution of the nitrate of silver, or with diluted muriatic acid; some surgeons particularly recommend the oxymel ærginis, and others the black wash, or a strong solution of the chloride of soda.

It would appear from Mr. Carmichael's researches, that these forms of syphilis, comprising those termed *papular*, *pusular*, and I might add, *tubercular*, do not require any mercury in their early stages, though it is admitted, that, in all of them, after they have lasted a certain time, mercury will come in beneficially, bring the patient completely out of danger, and do what it would not have done if given in an earlier stage of such diseases.

One observation, made by Mr. Carmichael, agrees with what I have seen, namely, that when the knee joint is enlarged and swollen from any cause connected with venereal complaints, you will never find that mercury will do any good, but, on the contrary, will make the case worse than ever.

With respect to the treatment of the phagedænic ulcers, which occur in the *advanced* stages of syphilis, and generally accompany or follow the tubercular eruption, they are certainly never benefited by mercury in their early stages. Some of these tubercles, affecting the skin, begin as ulcers, and scabs form on them, which assume a conical shape. In Mr. Carmichael's book there is a drawing of one of these conical scabs projecting from the forehead, so long as to resemble a horn. I believe that, in this form of disease, mercury is injurious; and that one reason why the osseous system is so often affected, is the exhibition of mercury in the commencement of phagedænic venereal ulceration. In the early stages, blood-letting should not be omitted, unless there be some peculiar symptom or condition of the health prohibiting it. Antimonials, saline purgatives, and small doses of the compound powder of ipecacuanha, may also be employed with advantage. In all cases of phagedænic venereal ulceration, opium and its different preparations are truly beneficial; indeed, I believe the most useful of all medicines. Sometimes opium may be combined with conium or hyoscyamus. The mineral acids are also frequently of particular service in the phagedænic varieties of syphilis; and the nitrous acid has long enjoyed very great celebrity.

When phagedæna affects the throat, the same general treatment will be of advantage; and, as for applications to the ulceration itself, you may use fumigations with the red sulphuret of mercury, or you may apply the black or yellow wash as a gargle, or touch the parts affected with the nitrate of silver. Another good plan is to touch the sore with

diluted nitrous acid, applied by means of a camel-hair brush. In many cases this plan has considerable effect in cleaning the sore. The solution of the chloride of soda is another application, which is now very much in favour. It is found, that phagedænic ulceration of the throat is sometimes disposed to extend to the larynx, and ulceration is then excited in the mucous membrane of that organ, and even necrosis and exfoliation of its cartilages. When you have reason to suspect this sort of mischief to be going on, you should apply a blister over the larynx, or rub the neighbouring skin with antimonial ointment, so as to produce counter-irritation. I should say, that in the treatment of the secondary symptoms attending this form of the venereal disease, you should always try alternative medicines, as antimonials, guaiacum, sarsaparilla, conium, the nitrous acid, or nitro-muriatic bath, &c., before having recourse to mercury; and you will find, that, under such treatment, the health will get into a more favourable state for the reception of mercury; and though at first you cannot advantageously give this medicine, yet, when the health is improved, it will become of important service, and, by giving moderate doses of it, you will bring the patient safely out of all his dangers.

The treatment of nodes, and of swellings, and pain in the periosteum, is to be regulated by the history of the case, and by attending to various circumstances, to which I have already invited your attention. When the pain or inflammation in a joint or bone seems to be more acute than belongs to the character of syphilis and true nodes, or those which follow that kind of primary ulcer which is called the Hunterian chancre, then you should have recourse to alternative medicines. The best plan is, to apply leeches to the integuments over the inflamed portion of bone or periosteum; and use fomentations and poultices, with aperient and antimonial medicines, or small doses of the compound powder of ipecacuanha. Such treatment will mostly give considerable relief. After the affection has been rendered more chronic, if it be still obstinate, try blisters, which may sometimes be kept open with advantage for two or three weeks. In some cases, pus will form under the periosteum, and then nothing will afford relief but making an incision, and forming an outlet for the matter that is confined.

True nodes require a mercurial course, but this only in moderation, and, generally, if you were to use all the blue ointment in Apothecaries' Hall you would not completely disperse them by this means. It is completely an erroneous notion, that mercury will bring down the bones quite to their natural level; this cannot be done by any kind of mercurial course. If, therefore, after you have given mercury to a certain extent, you find that the nodes become stationary, that all pain has ceased, and all appearance of specific action is at an end, the practice should be changed,

and local measures principally trusted to. Of course, at this period, the patient's health is, for the most part, a good deal reduced, and therefore you are called upon to endeavour to rectify whatever derangement of the constitution may be obvious. Such derangement is partly, perhaps, the effect of syphilis, but certainly, in many instances, more the effect of the mercury that has been given. You may, therefore, give the compound decoction of sarsaparilla, bark, or the sulphate of quinine, with or without the mineral acids; but, as for the nodes, trust chiefly to local treatment, and with this view, you can try frictions with mercurial ointment over the part, or with an ointment, composed of ℥j. of mercurial ointment and ℥j. of the hydriodate of potass, or ℥j. of the tincture of iodine, blended with an ounce of soap liniment. Many practitioners prefer covering nodes with the empl. ammoniaci cum hydrargyro; others apply soap plaster, but, when you want to produce much effect on them, you must use either iodine embrocations, or blisters, kept open with savine ointment. When the surgeon trusts chiefly to internal treatment, it is perhaps a good plan to cover the node with soap plaster, or the emplastrum ammoniaci cum hydrargyro.

The last venereal case, which I intend to bring under your notice, is that *variety of the disease which is seen in infants*. I have already mentioned to you, that syphilis is occasionally communicated to the fœtus in utero, through the medium of the blood of the mother. The effects of the syphilitic poison, thus developed in infants, may be said therefore to be secondary ones, as they arise from the introduction of the poison into the circulation of the fœtus, such poison not having been applied directly to the parts affected;—of course then, the fœtus must receive the infection through the medium of the blood. Whether the child is ever primarily affected, that is, whether at the time of birth it ever contracts syphilis, in consequence of the direct application of the virus of a chancre, with which the urethra happens to be affected, is a questionable point. Where the infant is actually *born with the disease*, the latter mode of communication is of course impossible. I have told you, that, in adults, with the exception of the parts of generation and of the mucous texture of the eyeball and eyelids, the venereal virus will not operate upon the general surface of the body, unless there has been some excoriation, or wound at the period of its application. But if it be the fact, that an infant may contract a primary sore on any part of the general surface of the body, by such part coming in contact with venereal matter in the birth, then the remark, which I have told you applies to adults, cannot be extended to infants. But I believe that few or no unequivocal cases, illustrative of this mode of communication from the adult to the child, are on record. I am far, however, from denying the possibility of such cases.

The symptoms of syphilis in the new-born child, or soon after birth, are mostly universal desquamation of the cuticle, which peels off very extensively and freely; copper coloured blotches and scaly eruptions over a considerable part of the body; various rednesses and superficial ulcerations about the anus and nates, and sometimes about the parts of generation; also ulcerations and fissures at the corners of the mouth, and in the mucous membrane of the fauces, and sometimes on the eyelids. Besides these symptoms, there is frequently an obstruction of the nostrils, with a thick yellow secretion, so that the child cannot breathe freely, and the respiration is attended with a snuffing noise. There is also an extraordinary degree of emaciation, the infant continuing to lose flesh daily, and, if not speedily relieved, it soon perishes. Abroad it is usual, in these cases, to give mercury to the mother, so as to affect the infant through her; but here it is found so easy to cure the disease by certain preparations of mercury given to the child, that the latter plan is commonly adopted. In this country the disease readily yields to small doses of calomel, about half a grain for a dose, or to five grain doses of the hydrargyrum cum creta; the latter, as the mildest preparation, is perhaps the better medicine of the two; it hardly ever fails.

On the subject of the influence of syphilis, an interesting question arises, whether the child, that has received the infection from its mother in the womb, is capable of communicating the disease to others? We find many cases on record of wet nurses having become diseased by suckling children thus affected, and, if the statement be correct, this is rather an interesting fact; for syphilis exists in such infants, as it were, in the secondary form, and the occurrence would therefore prove, that syphilis, even in the secondary form, is capable of propagating itself, which is at variance with the Hunterian doctrines, and with what is commonly believed with reference to its nature in adult subjects.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833-34.

LECTURE V.

Pathology and Treatment of Gastritis.

GENTLEMEN,—There is one point connected with the treatment of gastritis which I have not yet touched upon—the use of blisters; and as this is the first time I have spoken of them, I shall make a few remarks on their general application.

It is a great error to think that blistering is a matter of course in inflammatory diseases, or that the proper period for their application should not be carefully marked. It is a common idea, that if a blister does no good it will

do no harm; that it is probable some benefit may result from its employment, and that you may try it at all events. I need not tell you that all this is wrong, and that we must be guided by exact principles in this as well as in every other part of practical medicine. I am afraid there is a great deal of loose reasoning and empirical practice connected with this subject, even at the present day. Here is the general rule by which you should be invariably guided. No matter what kind of disease you have to deal with, if it be inflammatory, blistering in the early stage of it is decidedly improper. I might amplify this rule, and say, that if the disease be inflammatory and in its early stage, or if, under such circumstances, the symptoms require the general or local abstraction of blood, blisters cannot be used with propriety. The truth is, that many persons take a very limited view of this subject; they look upon blisters as merely revulsive agents, which, by their action on the surface, have the property of diminishing visceral inflammation. This I am willing to allow is true to a certain extent, but there is abundant evidence to prove, *that blisters have sometimes a direct stimulant effect on the suffering organ.* That this occasionally occurs has been established by many facts in medicine; and I have not the slightest doubt, that the application of a blister over an organ in a state of high inflammatory excitement will certainly be productive of injurious consequences. But if you apply them at the period when stimulation is admissible and useful (and there will always be such a period in every inflammation), you then act on just principles, and will generally have the satisfaction of finding your practice successful. The greatest empiricism is sometimes practised in the application of blisters to the head in acute inflammation of the brain. You will see, in Mr. Porter's admirable work on the Pathology of the Larynx, how strongly he is opposed to the early use of blisters in acute laryngitis. Dr. Cheyne, also, may, among many others, be quoted in support of this doctrine.

If there is one system more than another likely to be injured by early blistering, it is the digestive. Broussais says, that blisters should not be applied in any of the stages of acute gastro-enteritis, and that in the early stage their application is the very height of malpractice. I do not go so far as to say that they should not be applied in any period of the disease, for when the skin is cool, the pulse lessened, and the local inflammation so far reduced as not to require the abstraction of any more blood, I think you may employ them with very considerable advantage. I shall again return to the subject of blisters; and will for the present merely remark, that blistering is almost always mismanaged, in consequence of persons who apply them being ignorant of their stimulating effects on organs. They generally allow them to remain on too long, and the consequence of this is often violent excitement of the organ over which they

are applied, great constitutional irritation, strangury, and bad sores. The best mode of using them is to direct the person who prepares the blister to cover it with a piece of silver-paper before it is applied, and having put it on with the paper next the skin, to let it remain until a decided sense of smarting is produced, when it should be immediately removed. By adopting this plan, you will save yourself and your patient a great deal of inconvenience; you will have no strangury, stimulation of the whole economy, or excessive local irritation, and the inflamed surface will heal kindly. The mode (too often practised) of applying a blister sprinkled all over with an additional quantity of powdered cantharides, and leaving it on for twelve, twenty-four, or even thirty-six hours, particularly in the case of females, is nothing better than horse-doctoring. During a seven years' experience in the hospital at Tours, Brettonneau, by attending to this principle, never had a case followed by these troublesome symptoms, and yet he never failed in producing the necessary degree of counter-irritation. The active principle of cantharides, being soluble in oil, exudes through the silver-paper in sufficient quantity to produce the necessary effect on the skin, without exposing the patient to the risk of having too much irritation excited by the direct application of the blistering plaster to the cutaneous surface.

With respect to emetics, I need not tell you that they can be very seldom used in acute gastritis, and that all your efforts should be directed to obviate and remove vomiting. But are we to interdict their use altogether? There are some few cases where we are compelled to use them; as for instance, in cases of acute gastritis caused by swallowing corrosive poison, by the irritation of indigestible food remaining in the stomach. The first step, to be taken in a case of corrosive poisoning, is to evacuate the stomach. In the same way, when you are called to treat a case of gastritis produced by indigestible aliment, you must commence by giving an emetic. But even here the emetic is admissible only in the early period; and you should never trust to its operation for removing the gastritis altogether, unaided by other therapeutic means; nor are you to conclude, that because you have produced vomiting you have succeeded in curing the disease. The same principles apply to the use of purgatives in enteritis as to emetics in gastric inflammation;—we should never have recourse to them except where inflammation is kindled and kept up by the presence of irritating matter.

There are two cases in which certain affections are complicated with an acute gastritis; and as these complications are not sufficiently known, and have been scarcely noticed by systematic writers on gastritis, I am anxious to draw your particular attention to them. One of these is *Hæmatemesis*, the other that disease which has been termed *delirium tremens*. There are cases of vomiting of blood,

which are little more than acute gastritis, in which there is a copious secretion of blood from the mucous surface of the stomach. Vomiting of blood may arise from various causes. It may be vicarious, as in the case of females, where the menstrual flux is suppressed; it may be accidental, as from the rupture of a blood-vessel; or it may be caused by mechanical obstruction to the circulation, either in the liver, spleen, heart, or lungs. But there is a species of gastritis, in which there is a copious vomiting of blood; or there is an hæmatemesis, of which the cause is gastric irritation. How are you to recognise this form of the disease?—The patient is vomiting blood; but then he has fever, hot skin, and excited pulse. Again, you will see some peculiar modification of the tongue; you will find ardent thirst and longing for cold drinks; you will observe fulness and tenderness of the epigastrium; you may have severe local pain; finally, you will have all these symptoms occurring in a person who, previously to the attack, exhibited nothing capable of accounting for the hæmatemesis. Here, then, we have an hæmorrhagic gastritis, very little known, and too often improperly treated. The ordinary practice, in such cases, is to give astringents. Astringents are very good and useful where they are clearly indicated; but there are many forms of disease where their routine employment is productive of a great deal of mischief; and I believe lives are sometimes lost by looking upon this affection as a simple hæmatemesis, and by practitioners contenting themselves with the use of astringents. But where you have the symptoms of this form of gastric irritation present, where, in addition to the vomiting of blood, you have fever, and thirst, and hot skin, and pain, and epigastric tenderness, you may be sure that it is a gastritis, and that the best treatment is leeches, iced water, and the other means recommended in the treatment of gastric inflammation. It may happen that, under this treatment, the vomiting of blood will not entirely subside; but the pain, the thirst, the fever, and epigastric tenderness will subside, and then you can with propriety give astringents. The best thing you can do in the commencement is to leech freely, give iced lemonade, and cold water; prohibit every thing purgative, stimulant, or astringent; and then, when you have reduced inflammation, if the hæmatemesis continues, have recourse to astringents.

A few words now with respect to the other complication,—delirium tremens. You have all seen cases of delirium tremens, but you are not, perhaps, aware that it arises under two opposite classes of causes. In some cases, a patient who is in the habit of taking wine or spiritous liquors every day in considerable quantities, meets with an accident or gets an attack of fever. He is confined to bed, put on an antiphlogistic diet, and in place of wine or whiskey punch gets whey and barley-

water. An attack of delirium tremens comes on, and symptoms of high cerebral excitement appear. Another person, not in the habit of frequent intoxication, takes to what is called a fit of drinking, and is attacked with delirium tremens. In the first case the delirium arises from a want of the customary stimulus, in the second from excess. In each the cause of the disease is different; and consequently, with this view of the subject, it would be a manifest departure from sound practice to treat both cases in the same way. Yet, I believe, this error is frequently committed, even by persons whose authority is high in the medical world, and is part of a system not yet exploded,—*the system of prescribing for names and not for things*. The patient is treated for a disease which has been called delirium tremens, the present symptoms are only attended to, and the cause and origin of the affection are overlooked. What are the true principles of treatment?—In the first variety, where the delirium is produced by a want of the customary stimulus, there is no doubt that patients have been cured by the administration of the usual stimulants, by giving them wine, brandy, and opium. Indeed this seems to be the best mode of treating this form of the disease. But is it proper or admissible in the second variety, where the delirium is caused by an occasional excess in the use of ardent spirits?—Certainly not. Yet what do we find to be the ordinary practice in hospitals when a patient is admitted under such circumstances?—A man, who has been attacked by delirium tremens after a violent debauch, is ordered a quantity of porter, wine, brandy, and opium; and the worse he gets, the more is the quantity of stimulants increased. Now this practice seems to me as ridiculous as the old principle of treating a case of hydrophobia with a hair of the dog that bit. Let us consider what the state of the case is.—A large quantity of stimulant liquors have been taken into the stomach, the mucous surface of that organ is in a state of intense irritation, the brain and nervous system are in a highly excited condition from the absorption of alcohol, or in consequence of the excessive sympathetic stimulation to which they have been subjected. Are we to continue this stimulation?—I think not. What would be the obvious and natural result?—Increased gastric irritation, encephalitis, or inflammation of the membranes of the brain. The supervention of inflammatory disease of the brain in delirium tremens is not understood by many practitioners, and they go on administering stimulant after stimulant, totally unconscious that they are bringing on decided cerebral disease. I have witnessed the dissections of a great many persons who died of delirium tremens, and one of the most common results of the dissection was, the discovery of unequivocal marks of inflammation in the brain and stomach. Broussais considers all such cases as merely examples of gastritis, and ridicules British practitioners for

inventing "a new disease;" but in this he is certainly wrong, for there have been several cases in which no distinct marks of gastric inflammation could be discovered. In all cases, however, where the delirium supervenes on an excessive debauch, there is more or less of gastritis; and though it may occasionally happen, that a patient under such circumstances may recover under the stimulant treatment, yet I am convinced that the physician will very frequently do harm by adopting it.

This complication of delirium tremens with gastritis is also exceedingly curious in another point of view, as it illustrates how completely the local symptoms are placed in abeyance, and, as it were, lost during the prevalence of strong sympathetic irritation. The patient's belly will not be tender; the tongue may not be red; the symptoms present may be indicative of a mere cerebral affection, and yet intense gastric inflammation may be going on all the time, and all the appearances of cerebral disease be quickly removed by treatment calculated to subdue a gastritis. Is this all theory? No; for we have practised on this principle with the most extraordinary success in the Meath Hospital. We have seen cases of violent outrageous delirium subside under the application of leeches to the epigastrium, and iced water without a single drop of laudanum. I beg of you, if you meet with any cases of delirium tremens under such circumstances, to make trial of this mode of treatment, and record its effects, for it is important that they should be more extensively known. I have seen the whole train of morbid phenomena, the delirium, the sleeplessness, the excessive nervous agitation, all vanish under the application of leeches to the epigastrium. In some cases where after the sleeplessness and delirium were removed by this practice, and the tremors alone remained, we have again applied leeches to the epigastrium, and succeeded in removing the tremors also. On the other hand, where a stimulant plan of treatment was employed, and the patients died, we have most commonly found inflammation in two places, in the stomach, or in the brain or its membranes. The rule, then, is this,—in a case of delirium tremens from the want of a customary stimulus, use the stimulant and opiate treatment; but when it comes on after an occasional violent debauch, such remedies must be extremely improper. Adopt here every thing calculated to remove gastric irritation. We have facts to show that most decided advantage may arise from the application of leeches, even where the symptoms of gastritis are absent.

We come now to consider chronic gastritis, an extremely interesting disease, whether we look upon it with reference to its importance, its frequency, or its Protean character. It is commonly called dyspepsia, and this term, loose and unlimited in its acceptation, often proves a stumbling block to the student in medicine. Dyspepsia, you know, means dif-

icult digestion, a circumstance which may depend on many causes, but perhaps on none more frequently than upon chronic gastritis. In the great majority of dyspeptic cases, the exciting cause has been overstimulation of the stomach, either from the constant excess in strong highly seasoned meats, or indulging in the use of exciting liquors. Persons, who feed grossly and drink deeply, are generally the subjects of dyspepsia; by constantly stimulating the stomach they produce an inflammatory condition of that organ. Long continued functional lesion will eventually produce more or less organic disease; and you will find, that in most cases of old dyspepsia there is more or less gastritis. But let us go farther, and inquire whether those views are borne out by the ordinary treatment of dyspeptic cases. When you open a book on the practice of physic, and turn to the article dyspepsia, one of the first things which strikes you is the vast number of cures for indigestion. The more incurable a disease is, and the less we know of its treatment, the more numerous is the list of remedies, and the more empirical in its treatment. Now the circumstance of having a great variety of "cures" for a disease, is a strong proof, either that there is no real remedy for it, or that its nature is very little understood. A patient afflicted with dyspepsia will generally run through a variety of treatment, he will be ordered bark by one practitioner, mercury by another, purgatives by a third, in fact, he will be subjected to every form of treatment. Now all this is proof positive that the disease is not sufficiently understood. What does pathology teach in such cases? In almost every instance where patients have died with symptoms of dyspepsia, pathological anatomy proves the stomach to be in a state of demonstrable disease. It appears, therefore, that, whether we look to the uncertainty and vacillations of treatment, or the results of anatomical examination, the case is still the same; and that, where dyspepsia has been of considerable duration, the chance is that there is more or less of organic disease, and that, if we prescribe for dyspepsia neglecting this, we are very likely to do mischief. I do not wish you to believe that every case of dyspepsia is a case of gastritis. This opinion has brought disgrace on the school of Broussais. His disciples went too far, for whether the gastric derangement depended on nervous irritation, or anæmia, or disease of the liver, or mental emotion, they prescribed leeches and water diet, and thus very often brought on the disease they sought to cure. We may have functional disease, independent of structural lesion in the stomach, as well as in any other organ; it is no unusual circumstance, and the practical physician meets with it every day. A great deal of confusion, however, arises from the similarity of the symptoms. I remember an accomplished friend of mine getting into disgrace with one of the members of a board of examiners on this subject. He

was asked to tell the difference between the symptoms of chronic gastritis and dyspepsia, and in reply stated that he could not. For this he was nearly rejected, but I believe, on a candid review of the circumstances, you will agree with me, that he knew more of the matter than the learned professor. In ninety-nine cases out of a hundred of chronic gastritis there is no fever, scarcely any thirst, often no fixed local pain, and this leads persons away from any idea of the existence of an inflammatory condition of the stomach. What are the symptoms of a chronic gastritis? pain of occasional occurrence, flatulence, acidity, swelling of the stomach, fetid eructations, sensation of heat and weight about the epigastrium, and perhaps vomiting. Well, these are also the symptoms of dyspepsia, whether it be accompanied by inflammation or not. How then, when called to a case of this kind, are you to determine the point? I must mention to you here, that it is often hard to do this with certainty. There are two circumstances, however, which you should always bear in mind, as they will afford you considerable assistance in coming to a correct diagnosis; *first, the length of time which the disease has lasted*; secondly, the result of the treatment which has been employed. You will find, that where the disease is a chronic gastritis, that it has been of some duration, that it has come on in an insidious manner, and that it has been exasperated by the ordinary treatment for dyspepsia. Many persons think, that if you give a patient medicine, without regulating his diet or issuing a prohibition against full meals, that you can cure him, and that, as he has no fever, and can go about his usual business, there is no necessity for antiphlogistic regimen. But as the disease goes on, he complains of pain in the stomach during the process of digestion, feels uneasy after dinner, there is an unpleasant degree of fullness about the epigastrium, he also experiences a variety of disagreeable symptoms, sometimes being annoyed with pain in the chest, sometimes he says he feels it in the region of the heart, and sometimes about the cartilages of the eighth and ninth ribs. These symptoms subside after the process of digestion is completed, but during its continuance they harass the patient. Very often relief is obtained by vomiting, and hence some persons are in the habit of throwing up their food for the purpose of relieving themselves, and consequently can have no benefit by it. In some cases digestion goes on until the food seems to reach a particular point, and then an acute feeling of pain is experienced. In these cases the gastritis is generally circumscribed, and is likely to terminate in circumscribed ulceration. Various fluids are rejected from the stomach, during the course of a gastritis; sometimes acid, sometimes alkaline, sometimes insipid and sweet, sometimes bitter and bilious. There is generally a degree of fullness about the stomach, and the epigastrium is tender on pressure, but no decided tumour either of the

pylorus, liver, or spleen, although the epigastrium presented that appearance of fullness and tension termed by the French "*renitence*." The bowels, too, are constipated, and this is a matter worthy of your attention, for it sometimes unfortunately happens that the practitioner, mistaking the gastritis for simple constipation, goes on prescribing purgative after purgative, until the patient gets incurable disease of the stomach. I know a case of a lady who gets one stool a week by taking eight drops of croton oil. Some years ago, she was in the enjoyment of excellent health; her bowels happened to get confined, and she was treated by a systematic practitioner with continued purgatives; her bowels are now completely torpid, except when they are subjected to this unnatural stimulus. There are thousands of persons treated in this way, because practitioners look to consequences and not to causes.

There is one remarkable difference between acute and chronic gastritis, which deserves your attentive consideration, as it exemplifies a law applicable to all viscera under similar circumstances, and this is, that the sympathetic irritations are not so frequent or so distinct in chronic inflammation as in the acute form, and hence, in a case of chronic gastritis, we almost never have fever, and the affections of the nervous respiratory or circulating systems are by no means so well marked. It may even go on to actual disorganisation of the stomach, and yet the patient will not complain of any particular symptom during its whole progress, which you could set down as depending exclusively on the sympathetic irritation of gastritis. Some of these cases, called dyspeptic phthisis, by Dr. W. Philip, are most probably examples of the sympathetic irritation of the lungs from chronic gastritis. Another case, respecting which much error prevails, is what has been called hypochondriasis. Persons labouring under these affections are condemned to run the gauntlet of every mode of treatment, sometimes (and fortunately for themselves) they are sent to travel, sometimes they are treated with musk and antispasmodics, then with the mineral acids, then with purgatives and mercurials, and lastly with bark, nitrate of silver, and stimulants. They go about like spectres from one practitioner to another, trying remedy after remedy, alternately sanguine with hope or saddened by disappointment, until at last they die, and, to the astonishment of all the doctors, the only disease found, on dissection, is inflammation and thickening of the mucous surface of the stomach. A condition, which, under these circumstances, it was difficult to say whether it was the original disease, or produced by "*fair trials*" of a number of powerful agents. Hypochondriasis is not always gastritis; but it is now found, that in many cases it commences and terminates with disease in the upper portion of the digestive tube and the assisting viscera. This you must always bear in mind.

Chronic gastritis terminates in various ways. Sometimes the inflammation is limited to a particular spot of the stomach, and here we frequently discover circumscribed ulcerations. In very bad cases these ulcers go on perforating the various coats of the stomach, until at last the contents of that organ escape into the serous cavity of the abdomen, and the patient rapidly sinks under a fatal peritonitis. It does not follow, however, that, in all cases of perforation, the contents of the stomach get into the peritoneum, causing death. Very often adhesions are formed, and the base of the ulcer is the serous covering of some other portion of the digestive system, or a false passage may be formed into the colon. One of the most common terminations of a chronic gastritis is, that the inflammation extends to other viscera; the patient gets disease of the liver, spleen, peritoneum, or lungs, and sinks under a complication of disorders. It was somewhat in this way that Napoleon died. He laboured for a considerable time under chronic disease of the stomach, which seems to have been overlooked by his medical attendants, and this terminated in the extension of disease to various other organs.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XIII.

Ab lactation continued—Sleeping and Watching—Muscular Motion—Exercise—Placing an Infant on its Feet—Locomotion, or Walking.

GENTLEMEN,—At our last meeting I was describing the received opinions upon ab lactation, or weaning, when our time expired; and I shall now conclude the remaining observations on the subject.

It is very generally maintained, that the eruption of the teeth is a natural indication of the necessity of a more solid aliment than milk for the nutriment of infants, and that weaning should be commenced. As a general proposition this is a valid one, but, like all others, is liable to exceptions. It may guide us when the infant is healthful, but not when it is delicate or infirm. Every medical practitioner knows, that the process of dentition varies very considerably, as regards the time of its commencement; some infants have teeth before the sixth, and others no sooner than the twelfth or sixteenth month of their age; for the first, it would be too soon to advise ab lactation; for the latter, it would be too long to delay it.

Some writers hold that the age of an infant

is the best guide; but this cannot be followed, because constitutions and growth differ so widely, that an infant of six months old may be more vigorous than another of eighteen months. As a general rule, however, the propriety of weaning may be determined by the presence of the milk teeth, the vigour of the infant, the health of the mother or nurse, and the season of the year.

When the nurse becomes thin, delicate, nervous, dyspeptic, or when she labours under any acute or chronic disease, she will be injured by lactation; the infant will not obtain a sufficient nutriment, and consequently it will emaciate and become diseased. As a general rule, we may say, whenever the breast milk is altered in quality, or diminished in quantity, other food is necessary for the infant; and ab lactation must be commenced, or artificial aliment supplied.

The occurrence of pregnancy or menstruation, is generally supposed to alter the quality and diminish the quantity of breast milk, as in such cases the determination of blood to the womb, diminishes the supply of this fluid to the breasts, and consequently there is a less secretion of milk. This proposition, as a general one, is valid, but is of course liable to exceptions. Thus some pregnant women continue to supply an abundance of milk, even to the hour of parturition. Professor Dewees states positively, that he "has seen several instances, where children were suckled with impunity until others were born; and other cases more numerous, where children were weaned at the usual time, though the mother was some time advanced in pregnancy, without the smallest injury having been done to children so circumstanced; while others, again, were obliged to be taken from the breast at a very early period, in consequence of the injurious effects of deteriorated milk." The rule he lays down is this,—when the milk disagrees with the infant, ab lactation is necessary; when it does not, lactation ought to be continued for the usual period.

The same experienced author informs us, that he had seen infants applied to the breasts during continued and yellow fevers, without the slightest injury. This immunity was repeatedly observed in this country, during the epidemic or malignant cholera of 1832, as well as on many former occasions, and is known to all observant physicians. Nevertheless, these facts do not controvert the validity of the axiom, that the breast milk is deteriorated by all acute and chronic diseases, and its physical properties modified by the passions of the mind and the various aliments. It seldom happens that infants are applied to the breast during acute diseases or fevers, or suffered to receive aliment from this source only; indeed, common sense, as well as physiology and pathology, would oppose such a proceeding. As the infant receives other food besides the mother's milk in such cases, we must fairly infer, that we want more evidence to confirm

the conclusion, that it would escape injury and acquire sufficient nourishment under the existence of acute disease.

Some authors have entertained the position, that the degree of intelligence of an infant must influence our decision on the propriety of ab lactation. The degree of intelligence will depend upon the health of the infant in most cases, though it often happens that weak rickety children evince a greater portion of it.

Dr. Struve was of opinion, that weaning should take place at the sixth month, because, after this age, the mental faculties begin to expand, the recollection is stronger, so that the infant cannot easily forget the breast. There is some truth in this position; but the appearance of teeth, the state of the health, and the strength of the infantile constitution, and the other circumstances already mentioned, are our surest guides as to the proper period for ab lactation. It would be an injudicious practice to advise weaning, when the child's health is bad, while it is teething, or labouring under severe diarrhoea, or acute disease of any kind, as the breast is a certain source of tranquillity, a kind of sedative, in all the diseases and varieties of temper of infants.

When the infant is vigorous and lively, it may be allowed more solid food than milk, as soon as the teeth appear, and even earlier; and by accustoming it to this change of diet, and amusing it very much, it will forget the breast, and only require it occasionally during the day, and, after some time, once or twice at night. It is an objectionable practice to smear the nipple with bitter substances, such as softened aloes, soot, &c., to disgust the infant; a plan adopted by many of the lower and middle classes of society, and even recommended by Dr. Dewees. He advises us to excite the infant's aversion to the breast, by touching the nipples with some bitter or disgusting substance, as aloes, garlic, assafoetida, or covering them with a forbidding one, as black wool, ink, court plaster, &c. When the child is gradually accustomed to take other food, and very much amused by its mother or other attendant, it will forget the breast, or seldom require it; and therefore exciting aversion to it is unnecessary, and, in general, decidedly unnatural.

The change of diet from breast milk to other food deserves due consideration. The proper mode of nourishing a child, about to be weaned, is to exhibit bread and milk, not boiled together, but the bread steeped in boiling water, reduced to a pulp or pap, and tepid or warm milk added, with a small portion of loaf sugar. This may be given with a spoon, the head of the child being raised between the recumbent and erect positions, and nature will point out the quantity necessary for a repast. An excellent diet is composed of the gravy of any of the red meats, mixed with bread crumb, mealy potato, the starch of which forms most of the arrow-root of commerce, arrow-root, sago, tapioca, pearl

barley, semolina, rice, salep, &c. Let this be the principal diet, and the breast presented as seldom as possible.

The process of weaning is very much facilitated by allowing the infant to drink from a cup, which it seizes with avidity, care being taken, not to suffer it to swallow too rapidly, as whatever fluid it takes may get into the larynx, "go with the breath," and excite convulsive coughing. Milk alone, or mixed with a sixth part of tepid water, or tea, may be given in this manner. Though an infant may be allowed to drink from a cup or other vessel after the fourth or sixth month, it is bad it should do so at an earlier age, or when it is nourished by the breast, for this reason, that suction excites the secretion of saliva, which facilitates digestion, and is as necessary to an infant, as mastication is to an adult.

It is a great error to over-feed children at the time of weaning, or to exhibit solid food, such as meat of any kind. The farinaceous aliments already recommended are prepared, as if by mastication, for the action of the stomach; but solid animal food, however well minced, cannot be duly acted on by the gastric fluid. It passes partially changed from the stomach, irritates the bowels, causes griping, and excites scrofula, rickets, water in the head, consumption, and other diseases of the lungs. In fact, a child, even of two or three years of age, is injured by solid animal food, as the process of mastication is imperfectly performed, or, to use a popular expression, the child "bolts its food." Hence we daily observe gastro-intestinal irritation, depraved motions from the bowels, vitiated urine, enlarged abdomen, picking at the nose and lips, variable or voracious appetite, intense fever at some time of the day, infantile remittent fever, enlarged mesenteric glands, rickets, &c. These are the commonest diseases of children. If we inquire—has the mother been particular about the infant's diet, she usually replies in the negative, and says, "she allows it to take food with the family." This is acting contrary to nature and the laws of physiology, and hence it is followed by serious evils.

The last precaution I have to mention, with regard to ab lactation, relates to the season of year most congenial to this process. It would be manifestly improper to commence weaning in the winter, or in the early part of spring, because certain infantile diseases are most common at these seasons, and these would be aggravated by this process. The end of spring, the whole of summer and autumn, are therefore considered the best seasons for ab lactation.

The treatment of the nurse deserves attention. Mothers and nurses often suffer considerable inconvenience in weaning infants. The secretion of milk generally continues for some time, and may be abundant. It may distend the breast, and excite inflammation. To obviate or prevent these occurrences, the diet and drink should be di-

minished, the breasts partially drawn when distended, and fomented with a decoction of poppy-heads and chamomile, and afterwards smeared with warm almond or olive oil, and the bowels should be regulated every other day. The irritation of the bowels by purgatives will determine both blood and nervous influence, as in all cases, to these parts, diminish both in every other organ of the body, and consequently in the breasts, and therefore there will be less blood sent to these organs, and less milk secreted. Purgation is therefore one of the best means of suppressing the lacteous secretion. Some writers recommend the local application of vinegar and water, and others, belladonna and hyoscyamus. The following formula is strongly advised by Dr. Ranque, of Orleans, which, he says, will prove effectual in three or four days:—

R. Aquæ lauri ceras. ℥ ij,
Sp. æther. sulph. ℥ j,
Extract. belladonnæ ℥ ij.

A piece of linen, moistened with this lotion, is to be applied to the breasts three or four times a day.

This remedy is often effectual, but it sometimes fails. The German writers employ belladonna and hyoscyamus internally. I have lately tried this plan, at the recommendation of Dr. Belluomini, who has been administering the homœopathic medicines to some of my patients at St. John's Dispensary. He favoured me with a few doses of belladonna and hyoscyamus, but these had not the slightest effect in suppressing the milk. I may also add, that the homœopathic medicines were fairly tried in several cases at the dispensary, but without any benefit in a preponderating majority of instances. In some nervous and dyspeptic affections, they appeared to afford temporary relief.

The next part of the physical education or management of infants, which deserves consideration, is sleep and watching. Infants have great need of sleep during the first years of life. It is Nature's nurse, the soft restorer of strength, and of all fatigue caused by the constant motion of this age. Aristotle first observed, that, of all animals, man slept the most immediately after birth. A newborn infant does nothing but eat and sleep. Sound sleep is as necessary to its well-being as aliment. It sleeps when it does not eat, and it awakes but to take food. Some authors have held that it must not be allowed to sleep too much; but this is an error; for natural instinct will awake it when necessary. It is still more absurd to force sleep by violent rocking, or by soothing syrups, both of which induce cerebral congestion, or determination of blood to the head, which predisposes to hydrocephalus, and to many other diseases. The exhibition of wine or spirit of any kind not only causes the same effects, but irritates the stomach and bowels, and excites gastrointestinal inflammation. When the infant is

reared properly, and is in health, it requires no remedy to induce sleep; and it ought to be allowed to awake of itself. It is dangerous to awake an infant suddenly, as the disagreeable surprise, or the fright, might induce convulsions, and will inevitably injure the function of the brain, and, through it, that of every organ in the body. It is highly conducive to health, to accustom the infant to go to sleep and to rise at an early hour. Dr. Dewees advises to habituate it to noise, as the sense of hearing is not acute at birth; and hence, if the apartment is kept quiet, it may sleep too much. It appears to me, that there is no objection to accustom it to the ordinary noise, which is inevitable in the nursery, but I cannot assent to the latter sentiment. I agree with this able professor in the opinion, that the nursery should not be kept too silent, because the infant might be suddenly awoken by the slightest noise. There is no objection to accustom it to moderate noise; but any observant physician is aware of the great injury sustained by infants, when exposed to much or incessant noise. It ought to be placed in a dark, quiet situation, or it may be kept on the lap of the mother for a short time. Some authors advise the singing of soft monotonous airs to induce sleep, a practice first used by the Greeks and Pythagoreans, and since generally adopted. The monotonous humming of nursery tunes very readily induces sleep; and this state is further encouraged by gently patting the infant on the back, or any part of the body.

As a general rule, an infant may be put to sleep about a quarter of an hour after having taken the breast, or, when older, after his repast. In proportion as it develops and observes external objects, it has less need of sleep, and the period of repose, during the day, may be abridged, by attracting the attention and directing it to various amusing objects. When it awakes of itself, it should be allowed to remain in bed for some time afterwards, so that it may not be frightened when left alone. It should be accustomed to be put to bed and to rise early, as it generally awakes as soon as day-light appears. It is better that the bed should be rather hard than soft, and moderately warm, so as to induce a tranquil and restorative sleep. When the infant is a few months old, it will derive more benefit from sleeping by itself, than with its parents. It should be kept sufficiently warm; but, in cold weather, it often becomes so chilled, that it must be placed in bed with its mother, or nurse, in order to receive sufficient warmth. In such cases, the neck and chest of the parent, or nurse, will be uncovered, by the infant's being placed on her arm, and sliding down in the bed, and many women are attacked with cough and chest complaints from this cause. To obviate the danger of exposure to cold, the woman should wear a shawl, or warm bed-gown.

The position of the infant in bed deserves attention. It is usual to place it on either

side, but the right is preferable, especially after feeding, because this posture expedites the passage of the food through the stomach. In case of vomiting, were the infant on its back, it might be suffocated. It is also necessary to change the position of the infant very frequently, as, like an adult, it will become fatigued and inconvenienced by remaining too long in any posture. It has been held by some, that the lateral position is to be preferred, as it favours the escape of the saliva from the mouth, and that this is secreted in excess during dentition. This opinion appears to me to be of little consequence, and indeed untenable. It often happens, that the infant will turn on its face when left too long in one position, or that it will approach the mother too closely, which will expose it to the danger of suffocation, or, what is popularly termed, being overlaid by the mother. This is likely to happen when the parent sleeps very soundly, or after she has been deprived of rest for several successive nights, and is at length overpowered by sleep.

When the infant is kept too warm it perspires profusely, it becomes extremely susceptible of cold in the head, which renders the nostrils almost impervious, causing sneezing and snuffles, interrupts the respiration, disorders the brain and motion of the heart, interrupts the sleep, and completely prevents the infant from sucking. To obviate these derangements, the infant ought to be kept moderately warm, and a few drops of almond oil should be introduced into each nostril.

Dr. Underwood is of opinion, that young infants are often suffered to sleep too much in the day time, and that they should be gradually broken of it; "and, indeed, if not indulged, they will not be so much disposed to sleep as is generally imagined, and will therefore take more rest in the night, which is mutually beneficial to the child and the mother, who, especially if she suckle, will be less disturbed, at a time when she particularly requires the refreshment of sleep." When infants are sleepless in the night, he advises to keep them awake during the day, by playing with them, dandling on the knee, or amusing them. This advice I think should be adopted with some caution, for, if the infant is in good health, it will not sleep too much, and its repose should not be interrupted. Besides dandling on the knee is a dangerous and unsafe mode of exercise for a new-born or very young infant, and cannot in general be adopted before the second or third month, for the reasons I shall explain when describing exercise or motion. The same author is a strong advocate for the cradle, and contends that moderate rocking is not injurious: when the child is in health it does not require rocking in either a cot or cradle, and when it is feverish, its head and skin hot, such motion is highly injurious. An adult, affected with headach, cannot bear motion, neither can an infant. Rocking an infant to sleep produces bad effects on the brain; the infant sleeps

because it is stupified, it is in a state of stupor bordering on apoplexy; the digestion becomes impaired, the rocking, or jolting, occasions vomiting, alters the milk in the stomach, and causes violent griping; yet some infants are so accustomed to it that they will not sleep without it. There is no inconvenience in leaving the infant to repose in its cradle or cot, the inaction of its senses will induce sleep, and, if rocked at all, it should be very gently. This custom has, however, been universally condemned since the time of Galen. The position of the cradle, or cot, must be attended to; it should not be exposed to a vivid light, or placed laterally towards a window, as the infant would instinctively look to one side, and might acquire the disease called strabismus, or squinting. The same rule is to be observed with respect to the position of a candle or lamp in the nursery, but neither is necessary. Some contend that the infant should face the light; others that its head should be turned towards it; but all agree, that exposing it to a lateral light is improper. When it awakes from sleep, it is very improper to expose its eyes to a strong, or vivid light of any kind. It is a bad practice to cover the cot, or cradle, so as to exclude the air, which ought to have free circulation, because otherwise the breathing will become difficult and laborious, the child will gasp or sigh, its sleep will be disturbed, and finally it will be affected with fatal disease of the chest or brain. Children, of a year old, should not sleep in the same bed with their parents, when another can be procured, as they would be too warm, might be overlaid, or suffocated. Some writers hold it injurious to allow children to sleep with aged persons. They should not be spoken to at night, or carried about the chamber, as the mother, or nurse, will be exposed to cold, fatigue, and, finally, to various diseases. It is important to put the infant to bed at a certain hour, and it should not be awake, or taken up, during the night, unless to remove its dress when soiled or wetted. It generally awakes once or twice to take the breast, but soon falls asleep, unless spoken to. When it is deprived of sleep, it is either by mismanagement in dress, or diet, or by illness. The cause, whatever it may be, should be removed, and the effect will cease. It is highly improper to rock the cradle or cot with violence, or to exhibit narcotics, or soothing syrups, such as syrup of poppies, diacodium, sleeping drops, either alone or combined with wine, gin and water, or spirituous liquor of any kind, for the purpose of inducing sleep, as these will produce cerebral congestion, or determination of blood to the head, which may be followed by hydrocephalus, or water in the head, or by gastro-enteric irritation, which will induce vomiting, griping, convulsions, or fatal inflammation and ulceration of the bowels. It is most lamentable to observe the very common practice, among mothers and nurses, of violently rocking infants to sleep, and of ex-

hibiting narcotics for the same purpose. This class of medicines is extremely dangerous, and should never be prescribed but by medical practitioners.

When the nurse has occasion to suckle her infant, she need not sit up to perform that duty, because it is easily roused, and may not sleep again for some time. She can apply it to the breast, by lying on either side.

Though the infant requires clothing, food, and sleep, it also stands in need of motion, or exercise, without which it would soon cease to exist. Muscular motion is the chief means of accelerating the circulation of the blood throughout the body, on which the health of every part, and the due performance of every function, chiefly depend. The motion of the limbs and of the body depends on muscular action; and even the infant in the womb moves and exerts its muscles. Immediately after birth it moves and contracts its limbs, it breathes, it discharges the contents of its bowels and bladder, all of which functions are performed by the action or motion of a great number of muscles. We observe, that the infant, as soon as it is washed and dressed, stretches its upper and lower extremities, and here again it throws many muscles into action; its circulation, respiration, digestion, &c. are effected by the same power. It is, therefore, an error to maintain, that the body of an infant, at birth, depends entirely on its mother or its nurse for muscular action, or exercise, a want so essential to its welfare. It is, however, true, that the parent or nurse can excite muscular action in the infant by a moderate and proper exercise, by communicating a degree of motion with her arms, as in dandling in the arms, or on the knees, or by gently rocking it in a cot or cradle, or by using gentle friction over its body and limbs. These modes of exercise are extremely requisite for a new-born infant; but they should be employed with proper caution.

As soon as the infant is dressed, the nurse places one of her hands under its head, and the other on its back or breech, and supports it in a horizontal position; or she places its head and trunk on her lap, or on one of her arms, or carries it on a pillow round the room, which enables it to move its limbs, and enjoy the advantage of a free circulating atmosphere. It is highly necessary that the nurse, when carrying the infant in her arms, should frequently change it from side to side, and not hold it more on one side than the other, because, by so doing, curvature of its spine, and other deformities would be induced. Her own feelings oblige her to vary the position of the infant very frequently; but some nurses prefer holding it on one arm more than on the other; and when young, they are soon seized with pains in the back arising from the strained position of the vertebræ, which I have repeatedly known to terminate in lateral curvature of the spine. In such cases one of the nursery-maid's shoulders becomes elevated, or, to use a popular term, "grows out."

When the infant is placed in a sitting posture too soon, the weight of the head and body bends the spine outwards, or excruciates it, and forces the sacrum (the back bone at the lower extremity of the spine, and between the hip bones) inwards; and the same thing happens when the infant is held too long on the back. When placed too long with the face downwards, the pubic or front bones will be forced inwards; and if too long on either side, the hip-bone will be pushed in the same direction. These deviations of the bones may happen in scrofulous or rickety children, diminish the capacity of the pelvis so much, as to render parturition impossible without the aid of art, and often fatal both to mother and infant. The positions in which an infant is held are therefore much more important than superficial minds may imagine. It is manifest from the foregoing statements, that the posture of the infant, while in the arms of the nurse, should be frequently changed. It is a remarkable fact, that infants, unless when sleeping or taking food, are, from the earliest age, in motion, or making muscular action; so essential is exercise to their welfare.

The first kind of artificial exercise is carrying in the arms, for the infant requires to be almost in constant motion: this can be effected by dandling, patting on the back, body, or limbs, dandling by raising or depressing the arms, very slightly at first, and by rubbing the surface of the body and limbs night and morning. When the infant is about to be dressed, and after it is undressed, friction should be made over the whole surface of the body, a source of delight, as we observe by its countenance and its stretching its limbs. This mode of exercise can also be made on the lower limbs whenever the mother has occasion to change the napkin worn by the infant. The hand alone, a piece of soft flannel, a brush, and a comb, are the means most proper to make friction, both general and local. Some persons use hair powder on the hand or brush, but this is seldom necessary. It is also advisable to place the infant on a pillow or couch, or in bed, and allow it to move its limbs in all directions. As it advances in age it grows stronger, and will experience great pleasure on being frequently dandled; but care must be taken not to elevate or toss it too high, as it has an instinctive fear of injury, and under this movement makes convulsive gasps, or may be thrown into convulsions. The infant is often thrown very high, sometimes out of reach, and an attempt is made to catch it while descending; but this is a most dangerous practice, and may dislocate the neck or injure the chest by too much compression, or rupture, or otherwise injure the liver, spleen, or any of the viscera of the abdomen, or induce fatal inflammation or hæmorrhage, examples of which are on record. It has also happened, that the nurse or parent could not grasp the infant in its descent: it fell on the floor and was killed on the spot.

When the modes of exercise now described have been frequently tried, the infant, after a longer or shorter period, acquires a considerable power of its limbs; and if physically educated, or reared according to the established doctrines of physiology, it will be in good health, and will make attempts to assume the pre-eminent attitude of our species—the erect position. A question is now proposed to medical practitioners—How soon should the infant be placed on its feet? The answer to this question is not always easily determined. The proper time cannot be fixed, as it must depend upon the development and strength of the infant. Every physician has observed, that one infant will stand at the age of six, nine, or ten months; while another cannot do so at the expiration of double that period. We observe, in general, that healthful infants, when placed on a couch, bed, or on the carpet, move their limbs in every direction, gradually turn on one side or on the face, and after having supported themselves for some time on their hands, elbows, knees, or breech, they exert their muscles, and acquire strength by such motions in the neck and loins, and finally are enabled to assume the erect or upright posture. Great care is necessary to prevent them from injuring themselves by such motions; and to avoid falls, contusions, blows, &c., the French contrive a kind of guard-cap, which projects beyond the nose, and prevents injuries of the head and face. An infant should be allowed to stand as soon as it shows an inclination; but its body must be supported by the mother or nurse, when it first attempts to assume the erect position. This is usually done while it is being dressed, and also after that process is finished. It is a bad and unnatural practice to place an infant prematurely on its feet, because the weight of the body will bend or deform them. It should stand when it has power and inclination to do so, but no sooner.

When it assumes the erect position, the mother should give it proper support, by placing one hand across the chest, and the other under the breech; or by placing the open hands on the sides of the chest, below its arms. It is highly necessary to change the support very frequently; and not to permit too much weight on any of the bones of the infant, as these are imperfectly ossified, they will yield to pressure, and become deformed. Unless the body is supported, the legs will bend and “grow out;” if too much pressure is made on the sides of the chest, the breast bone will project, and the child will become what is popularly termed chicken or pigeon breasted. Besides the methods of support already described, the hands may be placed under the arms of the infant for a short time, while it exerts its lower extremities. These precautions are by no means so puerile as may be imagined; they are most essential to the proper exercise and growth of the infant.

Though the infant should not be placed prematurely on its feet, or assisted by leading

strings, go-carts, and such like contrivances, it would, on the contrary, be extremely improper to prevent it from attempting the erect posture, when it has inclination and power to assume it. All contrivances for supporting the infant only tend to cause deformities of its limbs and spine; because the inferior extremities, not being sufficiently ossified, will bend under the weight of the body, and the shoulders or chest must support the whole; the neck will become sunk between the shoulders and awry, and the shoulders elevated. It is only necessary to place the infant on the floor, carpet, or bed, when, after the series of motions already described, it will soon acquire sufficient muscular power to assume the erect position.

It has been urged by Dr. Hugh Smith, that the infant should be prematurely placed on its feet, because the lower animals assume this position immediately after birth. To this it is properly replied, that nature has fitted animals to accomplish this end, by making their bones solid. It should be always borne in mind, that the whole weight of the body of the infant, in the erect posture, rests upon its legs, whereas, in the animals, only one half of the weight is thus supported. Dr. Underwood has well observed, that if infants are left to their own spontaneous endeavours, no deformity will happen; and that it is by urging them to stand and walk by means of our own awkward contrivances, that mischief is produced. I may here observe that it is highly improper to secure female infants in chairs, or to leave them sitting too long in bed; as both practices induce rickets, and distortion of the spine, hip bones, and inferior limbs; thereby predisposing them to fatal labours at a future period of life. Hence the frequency of rickets and deformities among the children of the poor. The infants of the middle and lower classes are committed to the care of other children, or giddy young girls, who let them fall and injure themselves; or they are left sitting for several hours in bed, or fixed in chairs, causes which deform the back, enlarge the abdomen, distort the ankles, and bring on rickets. Such is generally the fate of children when sent out to nurse, as every experienced practitioner has repeatedly witnessed.

When children are rickety or delicate, they may be placed in a little chaise or go-cart, and take air and exercise in these contrivances.

From the preceding remarks it follows, that an infant will sooner or later raise itself into the erect position, and ultimately stand alone by taking hold of some external object. It should now be taught to move one leg before the other, and also to walk. It is much better that it should crawl before putting it on its feet, for all its muscles and organs will have obtained considerable strength. When it is taught to move its lower extremities, it must be supported by placing the hands under its arms, which is preferable to holding its dress or employing leading strings, both of which

compress the chest and abdomen, and do mischief. All rolling machines, on which the infant's hands are placed for support, expose it to falls and injuries, and are now generally condemned. The infant stands alone about the eighth or ninth month, and after it has been taught to move one leg before the other, its attendant should present some object to its view, which will induce it to attempt to walk; or she should hold it by the hands, or let it grasp her fingers, which is a much safer plan. Every care must be taken not to allow it to fall, or to have any object in its hand which might injure it. All infantile attempts at walking should only be continued for a few minutes each time; because the infant very speedily becomes sad at its inability, or fatigued by its exertion. A very slight fall may induce such injury of the brain as will cause death, or fracture of any of the bones. Thousands of children lose their lives, in consequence of the injury inflicted by falls or contusions; generally by congestion or water in the brain; and when we say to parents, "this child has had a fall," they then recollect, when too late, that such an injury had been sustained. Several children from a year and a half to five years old are destroyed by slight external injuries; and, therefore, we should impress this fact upon the minds of parents. Lastly, we should caution mothers and nurses against the practice of allowing infants to crawl on their abdomen, chest, or neck, as serious injuries may be done to the parent and offspring. Such pressure over the stomach, which is generally delicate, and over the breasts, which are extremely sensitive, is prejudicial to the nurse.

Children are extremely active while awake, and are instinctively fond of motion or exercise; but care must be taken, when they are very young, not to allow them to walk too much. They soon become fatigued, and require rest. In general, a child of three or four years of age, who is permitted to play about, takes a vast deal of exercise during the day, and falls asleep at seven or eight o'clock in the evening. It is therefore necessary to put it to bed, and, as it will sleep soundly, it usually awakes at daylight, or soon afterwards, and will wish to rise.

When the child is able to walk with the nurse, it should be recollected, that it must make three or four steps in proportion to one of hers; and the consequence will be, that, if too much fatigued, its hip or knee joint may be readily inflamed, and a most painful and destructive disease of the joint produced.

It is likewise highly improper to drag a child by the arm, and compel it to walk when it is tired, because its shoulder-joint may be so much injured as to become inflamed.

These precautions ought to be enforced on parents and nurses, as the neglect of them often does the most serious injury to children.

CONTINUATION OF THE REPORT UPON THE RE-ORGANISATION OF MEDICINE.

By the Commission of the Academy of Medicine of Paris.

TRANSLATED BY ALEX. THOMSON, M.B. OF ST. JOHN'S, CAMBRIDGE.

[THE great importance of the voluminous reports on the subject of Medical Reform in France compels us to abridge them, to the exclusion of other matter, as the meeting of parliament is so near at hand.—EDS.]

The reporter resumes, in a few words, the principal considerations he supported in the first part of this report, and then reads the legislative articles which resume the conclusions of the commission.

Articles of Legislation proposed by the Commission upon the question of the Officiers de Santé, or General Medical Practitioners.

ART. I.—The medical juries, created by the law of the 19th Ventose, an XI., for the examination and reception of the officiers de santé, are suppressed.

ART. II.—There shall be henceforth but a single order of practitioners, namely, doctors of medicine, or doctors of surgery.

ART. III.—The officiers de santé, received up to the promulgation of the present law, will continue to enjoy their right as heretofore.

ART. IV.—These officiers de santé may acquire the title of doctor, by means of an examination, a written consultation, and a thesis passed before a faculty.

ART. V.—There shall be in France six faculties, which shall have the right of receiving the doctors of medicine and of surgery, namely, one at Paris, one at Strasbourg, one at Montpellier, one at Lyons, one at Rennes or Nantes, and one at Bordeaux or at Toulouse.

The secondary schools of medicine actually existing shall be preserved. Two years' study in a secondary school shall be equivalent to a two years' study in a faculty.

ART. VI.—The examination and the reception of doctors shall no longer be intrusted solely to the members of the faculties. The medical men, practising in the city, and in the suburbs of the seat of the faculty, shall have

the right of entering, in the proportion of a third, into the composition of the jury of admission.

ART. VII.—The councils of the department shall have the power of paying for the expenses of a certain number of reception, on the condition that the candidates, admitted to enjoy this favour, are to establish themselves in a rural commune. If they quit that commune, they shall be bound to refund the amount of the expenses of their reception.

ART. VIII.—There shall be created, throughout France, cantonal medical men, in the localities where the want of them shall be recognised.

ART. IX.—There shall never be salaried medical men in the *chefs-lieux*, prefectorial towns of the departments, nor in the *chefs-lieux* of the cantons; but their real domicile must always be in a rural commune.

ART. X.—The cantonal medical men shall be chosen exclusively from among the doctors of medicine.

Articles of Legislation relative to Secret Remedies.

ART. I.—To date from the promulgation of the present law, there shall no longer be any secret remedies.

ART. II.—The inventor of a secret remedy shall alone have the right to a guaranteeing patent for the exclusive sale of his remedy, during a certain number of years, to be limited by himself.

ART. III.—That patents shall be delivered by the Minister of the Interior, but solely for remedies, and shall have obtained the approbation of the Royal Academy of Medicine.

ART. IV.—In order that a remedy yield to its inventor a right to a patent of guarantee, it must be well determined, first, that it is new, and secondly, that it is useful.

ART. V.—Changes in the form of compositions already known, or in the number of their ingredients shall not be admitted as new remedies.

ART. VI.—The sale and the retail of secret remedies shall not take place elsewhere than in the shops of apothecaries, lawfully received and furnished with diplomas.

ART. VII.—The patent shall be granted for ten, fifteen, or twenty years, at the will of the demander.

VOL. IV.

ART. VIII.—To obtain this patent the inventor shall be required to deposit two sealed packets containing the exact formula and the mode of preparation of this remedy, and also a specimen of that remedy prepared; the first packet at the office of the Secretary of the Minister of the Interior, and the second at the Royal Academy of Medicine.

ART. IX.—There shall be published every year, by order of Government, a complete catalogue of the secret preparations, of which the sale is permitted by patents of guarantee.

ART. X.—None shall counterfeit the remedies thus privileged under pain of damages, to be awarded by the tribunals.

ART. XI.—Every proprietor of a secret remedy shall be allowed to establish for it one or several dépôts throughout the kingdom, but exclusively with apothecaries.

ART. XII.—At the expiration of the patent the official journals shall publish the formula and the mode of preparing the remedy.

ART. XIII.—The brevet shall be null and void if it be proved, first, that the remedy is not new; secondly, that the inventor has given at the two dépôts, prescribed by Art. 8, an incorrect description; and thirdly, that he has contravened in some of its dispositions the present law.

ART. XIV.—The being declared null and void implies the loss of the tax for the patent, the restitution of which cannot be reclaimed.

[We were not able to catch the exact sense of ARTS. XV. and XVI., which, however, appeared to us of an importance altogether secondary.

ART. XVII.—That the tax for the right of patent vary according to the duration.

ART. XVIII.—The tax for a patent of five years shall be 500 francs (about 20l. sterling) for ten years 1000 francs, for fifteen years 1500 francs, and for twenty years 2000 francs.

Here follow two other articles imposing still further obligations upon the bearer of a patent; and finally, ART. XXI. declares the antecedent laws, and the decrees that are contrary to the present law, abrogated.

ROYAL COLLEGE OF SURGEONS.

Edinburgh, 4th January, 1834.

WE, the undersigned, Examinators to the University of St. Andrew's, and Fellows of the

3 G

Royal College of Surgeons of Edinburgh, do hereby protest against the Petition of the said Royal College to the King and Council, praying that the University of St. Andrew's may be interdicted from carrying into effect their late Regulations for conferring Degrees in Medicine and Surgery, and for the following reasons:—

1st. Because any exercise of the Royal Authority, so as to interfere with the Charter of any University, would be illegal and unconstitutional.

2nd. Because the alterations complained of in the mode of conferring Degrees are an improvement upon that which has been in operation since 1826. They insure a more efficient course of study, and a full and fair examination of the Candidates before they can receive the Medical Degrees.

3rd. Because the Royal College of Surgeons never attempted to interfere in regard to the affairs of the University of St. Andrew's, until it appeared likely that the *improvements*, made by appointing a respectable Board of Examiners, and enacting a most efficient course of study, would add so much to the value of the Degrees, conferred by the University of St. Andrew's, that the number of Candidates for these Degrees would increase, so as to effect the *pecuniary interests* of the Royal College of Surgeons, and more particularly of those members of that body who are Professors in the University of Edinburgh.

4th. Because it is absurd in the Royal College of Surgeons of Edinburgh, to object to the course of study required of Candidates by the University of St. Andrew's, seeing that it is nearly the same as that required by the said Royal College, and more extensive than that required to obtain Degrees in the Universities of Oxford, Cambridge, or Glasgow, or the College of Surgeons of London.

5th. Because it is evidently absurd in the Royal College of Surgeons to object to those certificates of attendance upon lecturers qualifying for a medical degree, which are received, not only by their own body, but by every other College of Surgeons in Great Britain and Ireland. In the Regulations of the University of St. Andrew's, published in 1826, it is expressly declared, that certificates of attendance upon lectures in any University,

or celebrated School of Medicine will be received.

6th. Because, according to the Regulations of the Universities of Edinburgh, Glasgow, and Dublin, it is impossible, that even the most distinguished members of the profession can receive what is termed the highest honours in medicine, without relinquishing their avocations, and attending as students for four years the elementary classes within the walls of a university, although they may have received a full course of medical education under the most distinguished teachers in the kingdom, as Sir Astley Cooper, Sir Charles Bell, Abernethy, Brodie, Guthrie, Lawrence, Elliotson, &c., &c.

7th. If the power of conferring Degrees in Medicine be limited to Universities, exacting attendance upon their own schools, either what may actually be the best schools must be deserted, or the persons who attend them must be excluded from professional honours. In other words, this would be to establish a monopoly, where monopoly, from every principle of humanity, is most to be deprecated, and to sacrifice, for the benefit of a few University Professors, the welfare of all classes.

8th. Such monopolies, and such exclusive privileges, are no longer required to promote the science of medicine, as the highest members of the profession, without these, have enrolled themselves in the lists of teachers.

9th. If the Regulations of St. Andrew's be carried into effect, the most salutary competition will be established between the *recognised public Medical Schools* and those of Universities, by which the science of medicine must be benefited, and the public good promoted.

10th. If the Universities do their duty, they have nothing to fear, possessing many advantages which their rivals do not enjoy. If they should relax in their exertions, there can be no reason why they should have exclusive privileges for their own *pecuniary* benefit, to the injury of the public.

11th. Degrees in Medicine are conferred in a manner similar to that of St. Andrew's, by the Universities of Oxford and Cambridge, and the petition, if applicable to the University of St. Andrew's, must be equally so to those of England, which, however, are not noticed in the petition.

12th. Because the Fellows of the College of

Surgeons, who have accepted the office of Examinators, have not in any manner infringed the declaration made on becoming members of that body.

In short, the alterations complained of are *improvements* on the mode of conferring Medical Degrees, in as much as 1st, the course of study, required, embraces every subject essential to the education of a medical man; 2nd, the student may procure that education in London, Dublin, Glasgow, Edinburgh, or any other Medical School of celebrity; and, 3rd, the Examinators have no *pecuniary* interest in the result of the examination.

WILLIAM GREGORY, M.D., F.R.C.S.E.

Reviews.

A Lecture Introductory to a Course of Lectures on Anatomy, Physiology, and Surgery. By G. D. DERMOTT, Lecturer on Anatomy, Physiology, and Surgery.

Thoughts on Materialism; and on Religious Festivals and Sabbaths. By HENRY BRADSHAW FEARON. 8vo. pp. 214. London: 1833. Longman and Co.

THE first part of Mr. Fearon's book is a proper subject for medical criticism, and we think it right to notice it, as we have Mr. Dermott's opinions now before us. Both these authors attempt to prove the materiality of the mind from Scripture, and both have in, our opinion, completely failed.

Mr. Fearon is evidently a writer of great research and learning, as is apparent by his historical sketch of immaterialism, and his criticism on the various translations of the Bible. In his historical sketch he introduces the immaterialism of the heathens, and asserts, without a shadow of proof, that the primitive Christians adopted this in believing in the immortality of the soul. He, however, makes

no allusion to the sacred volume in this part of his work; and he concludes the history without adducing references to the writings of the ancient fathers in support of his statements. He states that the fathers borrowed their views from paganism.

In his second chapter, he introduces organisation, and, like all materialists, makes this his strong hold; he copies from Mr. Lawrence, who copied very largely from others. We shall give a few extracts.

"We look to man, of whom we read in the Scriptures that he is made of the dust of the earth; that his Creator producing respiration by breathing 'into him the breath of life,' and thus imparting motion to his lungs, he became a living soul or person.

"We observe man at his birth, and during the first months of his existence, and we perceive the first dawns of his mind; that they are as weak and infantile as the body. As the senses acquire their power, the mind gradually strengthens, and advances with the body from childhood to puberty, and becomes adult when the development of the brain is completed. (Lawrence.) When the organisation advances, then the mind, as it regards its vigour and its natural powers, advances also. We observe this machine in infancy, manhood, in second childhood; we see its thinking powers grow, mature, and decay with the growth, the maturity, and decay of the organisation."

The correspondence between the mind, or soul, and body, does not prove their identity, nor does it apply to our first parents, whose bodies were created of the adult size, perfect in all organs, before they received life and soul, and whose minds were rendered adult in an instant. This fact cannot be questioned by our opponents, as both are believers in revelation. Behold these examples of a perfect organisation before the faculties of life and mind were communicated, and therefore organisation and mind are totally different from, and independent of, each other.

That the soul in infancy is no more than the body in a state of perfection, is no proof of its materiality; it has not as yet the power of acquiring the ideas that cause sensations; it cannot exercise its judgment, it has not formed or developed its different faculties. If when the corporeal organs are enfeebled, the soul also loses its vigour, it is because the sensations

are enfeebled with the organs that transmit them; and the physical sensibility enfeebles faculties, which have a close connexion. It would, however, be bad logic to contend, from the dependence or connexion of two things on each other, that they are identical. According to such reasoning, as all our organs are affected by disorder of the stomach, the stomach is all the other organs.

It is not invariably true, in the course of life, that the mind undergoes all the changes with the body. It is very true that the vicissitudes of the body often affect the mind; but it is equally true, that the mind is not always altered by the changes or diseases of the body. We often see children, feeble, delicate, and rickety, with much more ideas, judgment, and reason, than others that are better developed; we see the same thing in man; many robust and strong men have much less intelligence than those enfeebled by diseases. If diseases and old age sometimes enfeeble the mind; sometimes also in the decline or disease of the body, the mind does not lose all its energy and vivacity. We see this fact proved in the clearest manner in the last stage of pulmonary consumption, when the corporeal structure is nearly gone, and it was remarkable in malignant cholera, after the loss of circulation of the blood ceased for hours. Is it not also notorious that some men, who are strongly influenced by moral virtue and religion, conquer their temperament, or natural disposition, repress the most violent passions, reform the most tyrannical corporeal inclinations? This fact affords a new proof of the difference between mind and body.

If the corporeal affections were the unique principle of our spiritual qualities, should they not prevent men, who, actuated by a sense of duty or perfection, do that which is contrary to corporeal affections? Again, were the mind identical with the body, if it was the same substance, it would be only the body considered relatively to certain of its functions; or, as a part of the body, it should always undergo, and without exception, all the vicissitudes of the body. The same impulsion, given to the same body, necessarily impresses it with the same motion. So in the identity of the mind and body, the soul ought always to be, without exception or variation, as the body; the most vigorous body will then possess the strongest mind. The robust plough-

man should have more intelligence than the delicate philosopher. The legitimate conclusions, therefore, from the preceding incontrovertible facts, are, that the affections of the body are often communicated to the mind, because mind and body are two substances intimately united; but they do not constantly communicate, because the mind and body are different substances.

Mr. Fearon, like former materialists, takes one of his strongest objections from a comparison between men and beasts. He adduces many facts from natural history to prove what was admitted before by Pereira, Descartes, and many others, that the inferior animals have received from God, thought, ideas, memory, deliberation and judgment, and also an immaterial and pure spirit. Some of the ancient fathers were of this opinion. St. Augustin said positively, that beasts had souls, and that the principal difference between these and those of men was, that man could discern good from evil. (Enar. in ps. xx. 4, No. 2.) St. Gregory the Great distinguished three sorts of souls; that of the angel, which was not clothed with body, that of man united to body, and that of animals which perished with their bodies. (Greg. Mag. Dial. l. iv. c. 3.)

That which produces in animals operations which resemble those caused by human intelligence is instinct, which bears the same relation to these as reason does to man. It is scarcely to be believed that any materialist will seriously assimilate animal instinct and human reason. What an immense difference between these two things? Beasts have their inclinations, but each species has invariably its own and cannot form others. The most general and remarkable is the love of their offspring, which is a natural and necessary impulse, flowing from laws established by the Creator for the conservation of the species. Their habits are always the same from the beginning of the world. They are unable to invent or perfect. Their inarticulate sounds are formed by nature; their accents are as invariable as their operation. The language is the product of convention, convention supposes ideas, reason, and spirituality. Our ouran-outang, which approaches nearest to man in organisation, has the vocal organs well formed, but has not the faculty of speech. It brings a pitcher of water on its head to the door of its master, and unless some person is present to take the vessel,

the animal spills it, because judgment and reason are wanting.

Our author next discusses the scriptural proofs of the immateriality, spirituality, and immortality of the soul. He observes, that whenever the prophets or apostles reason upon the being and attributes of the Deity, they are clear, distinct, and intelligible. They are so on the forgiveness of sins, on repentance, a future state of existence by means of a resurrection.

"And can it be believed," he continues, "that had the materiality and mortality of the soul been a Bible doctrine, it would have been taught with equal plainness and distinctness? And if so, then would it have derived its chief support from popular ignorance, have called for aid from Socrates or Plato? Would its elucidation have depended upon Catholic councils or Protestant confessions of faith? or, like the system which Tillotson advocates, be required 'to be rather supposed than taken for granted.'"

"Neither Jesus nor the apostles required their adherents to take their principles for granted; and it is difficult, if not absurd, to conceive, that the whole foundation of the future hopes of the believer should rest upon a doctrine NOT EXPRESSLY TAUGHT IN THE BIBLE." The last assertion is unsuccessfully attempted to be proved by an examination of the terms *soul* and *spirit*, and the uses to which they have been severally applied by the translators of the Scriptures. He states, that the Hebrew *nephesh*, anima, spiritus, may be rendered, mind, soul, breath, life, body, person, will. The Greek *psyche* may be translated, breath, life, soul, spirit, mind, or person. The Latin *anima*, life, soul, breath, or wind. The word has a different derivation. The Hebrew *ruach* is rendered, wind, spirit, the power of the Deity, mind, vigour, life, breath, person*. The Greek word *pneuma* is translated, breath, spirit, wind, air. The Latin *spiritus*, breath, wind, spirit, mind, soul. Our author accuses the various translators of having adopted the popular doctrine of immaterialism, and allowed the authorised version to be deeply tinged with the corrupt theology of the state. He next quotes many

passages of Scripture, and after the word *soul* or *spirit*, he inserts, life, body, person, &c., so as to suit the text to materialism. His interpolations in most cases render the import obscure and untenable, as must appear to the meanest capacity.

According to a late learned scholar, the Greek word *pneuma*, or spirit, refers distinctly to the soul:—respiration, 2 Thess. ii. 8: the human soul, Matt. v. 3, 26, 41: of the soul after its departure from the body,—a spirit, soul, Acts xxiii. 8, 9; Heb. xii., xxxiii.: as referring to the qualities of the mind, Luke ix. 55: a simple, spiritual, incorporeal, intelligent being, spoken of God, John iv. 24: of angels, Heb. i. 14: of evil spirits, Matt. viii. 16; Mar. ix. 20: a divine spirit, spoken of the nature of Christ, 1 Cor. xv. 45; 1 Pet. iii. 18: of the holy spirit, Matt. iii. 16; xxviii. 19; John xv. 26; Acts i. 8; v. 3; Rom. ix. 1; 1 Cor. ii. 10, 11; Eph. iv. 30, &c., &c. See the Polymicrean Greek Lexicon to the New Testament, by W. Greenfield, editor of Bagster's Comprehensive Bible, &c., 1832. Numerous other texts might be quoted, but the following prove, in the clearest manner, the immateriality, spirituality, and immortality of the soul:—Wisdom ii. 23; Matt. x. 15, 16, 21, 22, 23; Gen. i.; Lev. iv. 17, 23, 26; Kings v.; Tob. iv.; Job. xiii.; Psalms ix., x., lxxxv., cxviii.; Cant. vii.; Eccles. x., xviii., xxiv., xxxviii.; Zach. xii.; John x., &c., &c. The word *mens* is employed to signify the intelligent substance—*mens cui regnum totius animi à naturâ tributum est*.

The remainder of the volume before us is occupied with a vain and fruitless attempt to subvert the doctrines of Christianity, and can scarcely make a single convert in an age so enlightened as the present. The introduction to the heathen doctrines of the immortality of the soul before the scriptural proofs, and the gratuitous assertion, that the Jews and primitive Christians adopted this doctrine, could scarcely be expected from any one who acknowledges the authenticity of the Bible—the eldest of all histories. Upon the whole, we consider this production calculated to do no good, and very little, if any, mischief. We shall now introduce Mr. Dermott's proofs of the materiality of the mind, and clearly show that they are as untenable as the preceding.

"Having stated thus much regarding the materiality of the mind, it is next my duty to

* Lardner gives these explanations, except the word *person*.

show that this doctrine is quite compatible with Scripture, and that many things mentioned in the Bible corroborate the theory which I advocate. To suppose that a person, favouring materiality, favours infidelity, is a notion begotten only by bigotry and ignorance. Surely the objectionists against materiality could never have read their Bible—if so, let me ask them—is it not in the power of Omnipotence, to make materiality immateriality, to spiritualise the materia vite or the material mind, or to so modify the latter as well as the material body itself, as to adapt both for an existence in another world. That such a change in our vital matter takes place is beautifully exemplified in the person of Jesus Christ; for when Christ appeared to his disciples subsequently to his resurrection, the doors being shut, he must have been spiritualised—body, life, and all—as the gross matter of a common human body could never have permeated the matter of the doors and walls; but when Thomas put his hand into his side, he was for the time miraculously materialised; and when he disappeared from the midst of them, and ascended to heaven, he was, like Elijah, miraculously spiritualised, as *we shall be* at the resurrection by an Omnipotent Power; for though Christ was the Divinity, still it is asserted that he was the first fruits of them that slept. This miraculous phenomenon is quite in correspondence with what St. Paul says in his second epistle to the Corinthians, chap. xv. 44.—‘It is sown a natural body; it is raised a spiritual body. There is a natural body, and there is a spiritual body. Howbeit that was not first which is spiritual, but that which is natural (material), and afterwards that which is spiritual;’ or, as the materialists might say, there is a material mind, and there will be a spiritual mind. Again: verses 51, 52.—‘We shall not all sleep, but we shall all be changed, in a moment, in the twinkling of an eye; for the trumpet shall sound, and the dead shall be raised incorruptible, and we shall be changed.’ For flesh and blood cannot inherit the kingdom of God; neither doth corruption inherit incorruption.—v. 50. Is not this transmutation in the power of Omnipotence? Let them answer this in the negative, and show moreover, that their negative reply is proved by assertions in the Bible, and then I will yield up my notions of materiality, and will believe that my finite reason may be mistaken

as to the works of the Creator in this part of organised life; but, until this is the case, I think that this apology for materiality, by all religious persons, should be considered valid. The days of religious inquisition are, I hope, past. The persecutions of the materialists, and stamping them gratuitously (not very graciously) infidels, resembles the persecutions against the illustrious Galileo, and even our own Newton, in reference to their material doctrines of the planetary system, and who were also stamped as materialist and infidels. I have mentioned these facts, to remove, if possible, the unnecessary strife now existing between materialists and some religious anti-materialists. The prejudice of many really well intentioned persons, in supposing that materiality is incompatible with Christianity, and that, therefore, a materialist must of necessity be an infidel, has tended, I believe, more than anything else, to check the diffusion of the belief of Christianity; and happy shall I be, if, under the dispensation of Providence, these observations shall tend in any degree to remove the barrier of separation between devout religionists and many men of science, and shall reduce materialism down to a mere scientific opinion, not at all affecting, in any important manner, religion. I deem these observations also necessary, because the prejudice against materiality may hereafter, if not corrected, seriously cripple the progress of Physiological Science.”

The apparent transmutation of the body of Christ from an immaterial to a material one, is no proof of the identity of mind and body. Many instances might be quoted from the sacred volume, to show that angels appeared in a corporeal form, and then became invisible to the human eye; but this is no evidence of the mutation of soul into body. It would be as just to contend, that as the Saviour fasted forty days and nights, and rose on the third day from death, that men can fast the same period, and rise on the third day.

The quotations from the Corinthians is the most splendid proof of the immateriality of the soul that could be adduced; and it obliges the materialist to admit a spiritual and a material mind. If, then, he admits the existence of an immaterial mind at the resurrection of the body, there is an end to all his arguments. We shall, however, proceed to prove the non-identity of mind, or soul and matter,

in our next, and defy all the materialists and phrenologists in existence to refute our arguments.

Mr. Dermott cannot be considered a materialist, in the usual acceptation of the term. He advocates the spirituality of the mind or soul at the resurrection, and does not believe that it dies and is corrupted with the body. In a word, he believes with St. Paul, that there is a spiritual and a corporeal body, but he has not clearly stated the nature of mind during life, and before the time of resurrection.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, January 18th, 1834.

DR. COPELAND in the Chair.

Excessive Discharge from the Nostrils of Limpid Fluid.—Want of Sleep from Acidity.—Tic Doloureux.

A RESOLUTION, to the following effect, was read, "That the name of every gentleman, desirous of belonging to this Society, should be submitted to the Committee previous to being balloted for." Some slight opposition was at first offered to this motion, but, on its being explained, that it was only a matter of convenience, the objections were over-ruled.

Mr. Costello then presented a projet de loi, received from a French physician, M. Double, a part of which appeared a fortnight since and another part in this day's Journal; he thought that the most proper mode of disposing of it would be to present it to Dr. Somerville, the mover of the Reform question.

Mr. King related a case which had occurred to Mr. Rees, of Finsbury-square, who had transmitted the notes to him:—

A female, *ætat.* 52, had excessive discharge of clear limpid fluid, from the left nostril, to the amount of a quart in 24 hours; it had commenced three months before, and was constantly secreted, night and day; it became necessary to wear a sponge, for the purpose of absorbing the discharge, as, from its constant trickling into the larynx, it had several times threatened suffocation; the patient is stout, but subject to excessive action of the sanguiferous system; her eye-lids are puffed; there is a florid state of the countenance; and a pulse of 96; she has a general disposition to

anasarca; and the catamenial discharge, which appeared at 10 years of age, and which has continued to flow ever since, is quite regular; her diet consists of vegetables; hitherto no local or general treatment has been found of avail.

Dr. Johnson said, the discharge was evidently a remedial, or, to use a modern word, conservative, process of the animal economy, to ward off disease; he did not think it would be proper to restrain it, but in such a case he should rather endeavour to discover and remove the cause.

Dr. King said, the circumstance of the discharge from the vagina having appeared at 10 years of age, and yet still continuing, although the woman was now 52, seemed to confirm the view taken by Dr. Johnson.

Dr. Johnson wished to draw the attention of the Society to a subject, which at first appeared very trifling, but which frequently baffled practitioners, and was the cause of great distress, and injury to the health; he alluded to the want of sleep, of which many persons complained, although apparently, in other respects, in perfect health, accompanied by starting of the limbs, and inability to lie long in one posture; the person having thus passed the night in great distress, rises in the morning unrefreshed. The cause of this want of sleep was, in his opinion, the existence of some acrid or acid matter in the small intestines; sometimes eructations, or discharge of gas, will take place, and then the irritation ceases for a time. The remedy for it is to guard against taking late meals, but as people will not always adhere to such rules, it becomes necessary to seek for other remedies, and none had he found so beneficial as carbonate of soda in half drachm doses, administered at night; frequently, after taking this medicine, six or seven hours' sleep had been obtained, whilst without it the patient had passed a restless night.

Dr. Copland confirmed the opinions of Dr. Johnson; he had found large doses of soda combined with anodynes particularly efficacious.

Mr. Greenwood thought that Dr. Johnson had taken a limited view of the case. The restlessness and want of sleep, in his opinion, were only symptomatic of some other disease, perhaps chronic duodenitis.

Dr. King coincided with Mr. Greenwood, that, if we dived deeper into the cause, it

would be found to arise from chronic inflammation of some portion of the bowels; the constant use of soda had frequently proved injurious, although the person using it extolled the effects; the urinary organs became disturbed, and deposits of saccharine matter to a considerable extent sometimes took place.

Mr. Hunt said the habitual use of soda was in the end injurious, and he questioned whether the presence of acid was not eventually increased by it. Dr. Prout coincided with him in opinion, and had been in the habit of carefully avoiding the use of this medicine after meals. He, Mr. Hunt, was in the habit of giving small doses, for he had observed that those persons who used it very largely, were pallid, and unhealthy looking.

Dr. Copeland agreed with Mr. Hunt, that the excessive use of it was injurious, but he did not consider that Dr. Johnson had recommended it in excess.

Dr. Johnson did not think the habitual and daily use of soda serviceable; but because it was not useful in excess, we were not to be prevented giving it when it was indicated by the presence of acid. If eructation of air took place after using soda, then we might conclude that acid was present; he was aware that, if we referred to the cause of the complaint, we must have recourse to bitters and tonics; but he had merely mentioned this distressing symptom as forming part of the disease.

Some remarks were then made by several gentlemen, as to the beneficial effects of this remedy in gout and rheumatism.

Mr. King wished to ask Mr. Costello, whether he had any objection to have the subject of lithotripsy brought forward for discussion.

Mr. Costello should rather decline entering into the subject for the present, as he was engaged with Dr. Civiale and Dr. Ammussat in preparing a work on the subject, and too much of his time would be occupied by such a discussion.

Mr. Hunt related the case of a gentleman, who had swelling of the right parotid gland, no pain in it, but a constant uneasiness, redness, tumefaction of the fauces, and difficulty of swallowing. The tumour at first appeared at the anterior part of the gland, it then would subside, and afterwards appeared at the posterior portion. He took the opinion of a

highly respectable dentist on the subject, who thought with him, that probably the existence of a tooth at the extremity of the jaw might be the cause.

Mr. Waite said he had agreed with Mr. Hunt in his view of the case; he let out some matter, and, after much trouble, succeeded in extracting a tooth, after which the tumour disappeared. He then entered into a lucid explanation of the anatomy and diseases of the gums, together with the sympathy existing between them and the constitution, to which sufficient attention, in his opinion, was not paid by surgeons in general.

Some cases, illustrative of the complaint under consideration, were related.

Mr. Waite made some remarks on the treatment of *tic douloureux*, and of the plan of treatment adopted by Mr. Scott, of the London Hospital, which was the employment of caustic, and which was reported to have been successful when other remedies had failed.

In the course of the discussion on this subject, the case of the Marquis of Anglesey was referred to by Mr. Waite and Mr. Costello, and as some erroneous notions, upon this subject, had obtained credence, Dr. Ryan, who had been consulted, was called upon for an explanation of the real state of the case.

Dr. Ryan replied, that he was induced to make the inquiry as to the period the noble Marquis was free from his distressing disorder, as he was aware that he had suffered severely from it immediately before he left this country for the continent. With respect to his, Dr. Ryan's, informing the Society of the history of the Marquis's case, he should have much pleasure in doing so, but he felt some hesitation in complying with the evident wish of the meeting, on ethical grounds only. If the President and members of the Society sanctioned his conduct in stating the outlines of the case, he should be most willing to do so.

Dr. James Johnson observed, that he saw no delicacy in the matter, the whole profession was aware of the disease of the Marquis of Anglesey, and the case of a marquis did not differ from that of any other man. The whole Society concurred in this opinion.

Dr. Ryan then said, that he was one of a great number who had been consulted in the case of the noble Marquis. He would very briefly describe the outline of his case. Many of the most eminent physicians and

surgeons of this and other countries were consulted, but, as a matter of course, took different views of the cause of the malady. Some considered it purely nervous; others, that it was excited by pressure on the facial nerves; more, that it was caused by concussion of the spine, induced by riding on horseback, an exercise to which the noble Marquis was extremely partial, and that, as the weight of the body was on one inferior extremity (the other having been lost at Waterloo), the spine was frequently concussed by the plunging of the spirited horses on which the noble Marquis was accustomed to ride, because whenever this occurred, though he might have been free from neuralgia for several days previously, the disorder was instantaneously excited. It was right to mention, that the disorder was much less severe since Sir James Murray, his experienced and judicious physician, had discovered some tumefaction in the abdomen, and successfully removed it. This arose from two alvine concretions; the nucleus of one was a mercurial pill covered with silver leaf; that of the other was a tea leaf. After these were expelled, the noble patient suffered much less from his complaint than at any former period since its supervention. Every remedy hitherto proposed by British or foreign physicians was fairly tried, but, unfortunately, with only temporary benefit. When the noble Marquis was last in London, and on the eve of departing from this country to the continent, Sir James Murray and himself, Dr. Ryan, most maturely deliberated upon the case, and he, Dr. Ryan, related some cases of neuralgia which yielded to the use of strychnine, and read the details from his note-book to Sir James, who promised to try the remedy. He had not since heard from Sir James, but entertains no doubt that he tried the strychnine. He, Dr. Ryan, therefore thought, that, under this circumstance, it was not quite fair to ascribe the mitigation of the disorder, if any took place, which he sincerely hoped there had, to the change of air only.

MEDICAL SOCIETY OF LONDON.

Monday, January 20, 1831.

W. KINGDON, Esq. President, in the Chair.

Perforation of the Stomach.

MR. MOORE related the following case, which had lately come under his observation. A

girl, æt. 15, tall and delicate, apparently in the enjoyment of good health, after giving a violent scream, suddenly became insensible. She was cold and pallid; the pupils were much dilated, and the pulse was scarcely perceptible; there was vomiting of a glairy matter. As the symptoms appeared to be those of compression, and as the pulse was small and feeble, he had given a stimulating and aperient clyster. By this treatment the system was slightly roused, and she was then bled: this blood was perfectly arterial in colour, and did not coagulate. Her hand was placed on the region of the stomach; and as this appeared to indicate distress in that viscus, a mustard poultice was applied. Dr. Clutterbuck saw the patient in the evening, and again prescribed venesection, which was performed, but without avail, for the next morning she expired. About thirty hours after death a very careful examination of the brain was made, but no traces of lesion or disease (with the exception of about a drachm of fluid in the ventricles) were found. In the stomach, about two inches from the cardiac orifice, there was an ulceration, without elevation, penetrating through all the coats, and allowing of the escape of some fluid into the peritoneal cavity. The mucous membrane was red, and was eroded for rather a greater extent than the muscular coat; and the peritoneum, upon which the fluid lay, was slightly rough, but in no other way injured by the contact. The fluid was rather acid, and on being strained through paper left a deposit of a fatty matter. Inquiries were made respecting her health previous to the occurrence of the foregoing symptoms, and from what could be ascertained, it appeared that she had been cheerful and in good health, with the exception of a slight loss of appetite. She had menstruated six months previous for the first and only time.

Dr. Whiting said, that the symptoms were so similar to those which occurred after the administration of some of the narcotic poisons, that it was not improbable but that she had taken some deleterious substance of this nature. It became a question whether the opening into the peritoneal sac occurred before or after death; if before, then no doubt it was the cause of that event; but it was difficult to account for the cerebral symptoms which were present; and it was from the existence of these that he considered, that she had been unfairly

dealt with—in fact, that poison of some kind had been administered.

Mr. Proctor considered it curious, that, as the symptoms certainly referred to the head, no appearances of disease were found there. From the examination, it would appear, that these symptoms were the result of the sympathy existing between the two organs, somewhat analogous to those produced by the presence of worms.

Mr. Kingdon said, that this case differed from the generality, for usually in perforations of the stomach we had time for observation, as the ulcerations were longer in their progress.

Dr. Williams thought, that disease must have been going on longer than would appear from the information which Mr. Moore had obtained. They all knew the little dependence there was sometimes to be placed on the statement of relations and friends in such cases, and he thought, in the present instance, a wrong statement must have been given.

Mr. Stevens perfectly agreed with Mr. Moore as to the perforation being the cause of death; but he had known several cases where symptoms of apoplexy had been followed by death, and yet no effusion of blood or serum was found on examination. In such cases, however, the sinuses were found gorged with blood.

Mr. Proctor spoke of the length of time required to occasion lesion of the stomach. He had seen, in cyder countries, vomiting and purging occasioned, and kept up for a considerable time, by the unlimited use of this liquor, and yet no ulceration or other ill consequences ensued. It would almost appear from this, that country stomachs and town ones were of a different nature.

Mr. Headland wished to know whether, in cases where the stomach had been perforated by the gastric fluid, Dr. Whiting had usually found the marks of inflammation.

Dr. Whiting said, colouring of the mucous coat was no criterion of inflammation, for it often existed when it was impossible to suppose that there was any inflammatory action present.

A Member thought, that the cerebral symptoms, present in this case, were exactly such as we might expect, from the sympathy which invariably exists between the head and stomach; he did not imagine that the blood

would be found of such a bright arterial colour in disease of the brain.

Dr. Uwins, after stating that too much value should not be placed on the appearances of the stomach, wished to know if ramollissement of the brain was capable of spontaneous cure, since from some observations which he had made, it would appear that such was the fact; but cerebral symptoms were not to be depended on, for in one case, where all the marks and signs of hydrocephalus were present, not the slightest appearance of disease was to be found; the brain was, however, slightly blanched.

Dr. Whiting thought, that the deficiency of blood in the head, in such instances, would be the cause of apoplexy or disease. He then related a case, in which a man had paralysis of one side, from which he partially recovered, but at the end of two years he had another attack, and died. On examination, in the hemisphere of the brain from which proceeded the original attack, there was found a small slit lined with an adventitious membrane.

Several cases of ramollissement were then related, after which the Society separated.

THE
London Medical & Surgical Journal
Saturday, January 25, 1834.

**MEDICAL REFORM.—RUMOURS OF
NEW OPERATIONS IN THE COL-
LEGE OF PHYSICIANS.**

WE do not claim the merit of originality for the communication we are about to make to our readers, nor can we pledge ourselves to its accuracy in every respect:—*valeat quantum valet*—certain it is that a rumour of some most important events being likely to occur in the College of Physicians is afloat; of which rumour we can trace the origin to “no one, neither man nor woman.” It is said, in the first place, that the learned President has made arrangements for entertaining his illustrious visitors at Pall Mall East, in more than the customary manner.

* See the Medical Gazette of last week.

Cards will be soon issued to those distinguished personages, and a certain number of the profession will be licensed to attend. Every member of the humblest rank must participate in the honour reflected upon the heads of his profession, by this agreeable *concourse* of all that is fashionable and eminent in church and state within the walls of its sanctuary: and his pride will be wounded in the tenderest point if the housekeeper should fail to supply tea and coffee of the most exquisite flavour for the distinguished coterie. We feel assured the learned President has not neglected this essential particular, as far as it falls within the duties of his office. Such matters may be trifles, but, as Horace saith, it is in these little things a master-mind is shown.

In order to give a professional tone to the conversation, not unsuited to the genius of the place, nor pedantic under the circumstances, essays upon medical topics of general interest will, without doubt, be occasionally read. The rumour, we have already alluded to, sanctions us in announcing, that the first evening's essay will be from the pen of the accomplished President himself; and that he has taken for his subject a matter most interesting at the present crisis. From his discriminating judgment and refined taste as a scholar, from his eminent success in his profession,—and presuming that success is in the compound ratio of skill and knowledge of the world, we may add,—from the extent of the learned President's medical attainments, and his profound anatomy of human character, we expect a most valuable essay on the education and duties of a physician.—On a late occasion, a French orator opened a debate, by assuring his audience that he had obtruded himself so early on their attention, only because the

explanation he had to make would save the Chamber from the trouble of listening to an infinitude of harangues from other members. Respect alone for the modesty of the learned President prevents us from attributing, by anticipation, the same result to the forthcoming essay. But, what a magnificent idea! With one grey-goose quill, or steel pen, or gold tipped with rhodium, to prescribe the laws of medical morals; to fix the limits of education, and harmonise the discordant systems of the medical corporations; to outstrip the dreaded operations of a parliamentary inquiry, by leaving nothing to inquire, or prescribe its foregone conclusions to a royal commission; to produce, in short, the Koran of professional education and ethics, and supersede the puny labours of journalists, of pamphleteers, of medical societies, and of the legislature! Should, however, the essay fail to accomplish these admirable effects,—should the storm which threatens the College not be allayed by the modifications of its laws which the same rumour informs us are in contemplation, the learned President, who has already enlightened his illustrious audience by an essay on Dying made Easy, or a Royal Road to Death, can add an interesting section on the Euthanasia of corporations, very much suited to the times.

We have said, that the same rumour informs us of certain modifications in the laws of the College of Physicians, which that learned body has in contemplation. This, second, and no less interesting, branch of this week's communication demands a few words in explanation. A Committee of Fellows is said to have reported its opinion in favour of an extension of education in the candidates for a licence. To such a change, we, who have uniformly contended for an improved

education, can have no objection. Absurd as the varieties of the new curricula are, the ambition of novelty, in their formation, is useful to the general cause; as every addition points at some defects, real or supposed, in the others, and leads to inquiry. The report is said to recommend a period of five years' study, an increased hospital pupilage, and an education in surgery. If the College of Surgeons should exact a corresponding education in medicine, as it must do in its own defence, if this report is adopted, we see nothing to prevent that happy amalgamation of the objects of the two Corporations, which we have already recommended. Every surgeon would be a physician and every physician a surgeon; this is the desired result, and it matters little how we arrive at it, whether by assuring the public, that the members of each distinct corporation possess the requisite qualifications, or, according to our plan, by insisting on every member of the medical profession belonging to both corporations, in their present distinct characters*.

With regard to the constitution of the College, the new plan, which is sanctioned by the Committee, consists, it seems, in this. The Fellows are to be *exalted* to a new station, not, indeed, in name, but in character. They are, as at present, to be essentially the *governing* body of the College, so that the names of Fellow and

Governor are to be synonymous: they are now, no doubt, the whole corporation; but every graduate of Oxford and Cambridge (and by an easy process of translation the privilege extends to Dublin) has a right to the Fellowship, and the number of Fellows is thus unlimited. By depriving the graduates of this privilege the number of the Fellows will be at their own discretion, and must be limited even below the standard of the present comparatively open system. If it exceeds the reasonable limits of a Court of Censors, or Council, we shall have the same assumption of superiority, which is intolerable at present, with the additional evils of a limited aristocracy. If the number is to be reduced to that of a council, we will not stickle about the title, but we have still to inquire, how is this council to be appointed? is it to be self-elective? Our readers will not be surprised to find this question answered by the Committee in the affirmative. The next alteration consists in *degrading* the present candidates for Fellowship into the mob of Licentiates;—English University Graduates are no longer to be dubbed inceptor candidates, or candidates, they are to sink into the rank of Licentiates; out of this olla podrida the Fellows are annually to coopt into their body such additional members for the government of the College, as the wear and tear of death, or other accident, may render necessary. A Licentiate must be of a certain standing before he can receive this favour—it is not to be a matter of right:—but the time of promotion for an English University Doctor is to be shorter than that of the other Licentiates, and he has, besides, in his favour, the chances of a proper understanding between the Fellows and Universities.

The pretended liberality of the College to the Licentiates, in its readiness to declare them eligible for Fellowships, if

* In our Leader of No. 102, an error of the press occurs, which we take this opportunity of correcting. The passage, in the second column near the bottom, should have stood—“If, now, the authority of the College of Physicians was extended over the whole kingdom, so that none should practise physic but such as were members of that corporation; and if it were required of every practitioner in physic that he should be a member of the College of Surgeons,” &c. In place of the last word was printed *Physicians*.

they, the Fellows, should think proper to admit them as a mere favour,—whilst it carefully abstains from acknowledging the right of the Licentiates to the honours of their profession,—has failed, on former occasions, in conciliating that degraded body. Three successive kings resolved, that a Licentiate, now full of years and honours, should hold the distinguished rank of their physician; his public services had entitled him to the confidence of his royal masters. Sir Henry Halford would have willingly extended the boon of a Fellowship to Sir Gilbert Blane;—we believe he repeatedly offered it, but the independent veteran refused to receive as a favour what he deemed to be his just right; and not his only, but the just right of every Licentiate of talents and experience.

Considering the authority we have for all this Reform, we must reserve our comments, if any further be necessary, for another occasion, till we see whether it may not turn out, after all, to be the mischievous drolleries of Nobody.

Foreign Medicine.

New Instrument for relieving Incontinence of Urine.

An instrument has been recently invented by Signor G. B. Chiesa, for the purpose of remedying the inconvenient apparatus now used for incontinence of urine; it is called the *urétrolibe*, or compressor urethræ, and consists of a small ring of silver, nearly elliptical, and consequently adapted to the shape of the penis; it is about an inch and a half in length, and half an inch broad, and is divided into three parts, which are united together by means of a screw; the middle segment is pierced in its centre by a small screw, having a well padded button at the extremity, which serves to compress the urethra, and by turning the screw allows the degree of pressure to be regulated.

Acceleration of the Pulse in deaf and dumb Persons exposed to a high temperature.

Professor Bernardino Mojon, of Geneva, in

feeling the pulse of persons covered with fire-proof metallic coats, and exposed to the flames for some minutes, constantly found, that, with those deaf and dumb, the pulse was increased twenty or thirty beats in the minute more than ordinary; whilst, with persons enjoying the sense of hearing, the pulse was augmented sixty beats, and even more. Thus, with the first, the pulse was from ninety to ninety-four, whilst with the latter it mounted as high as 130. From the preceding experiment the following question arises:—Does congenital deafness tend to diminish the organic sensibility? or does it so happen, that individuals, endowed from their birth with a slight degree of sensibility, cannot, on this account, enjoy the sense of hearing?

Experiments upon Digestion,

BY CARLO MATEUCCI.

Carlo Mateucci, desirous of following up the experiment of Dr. Wilson Philip, upon the influence of the Galvanic battery on digestion, &c., in which he perfectly coincides in opinion, devised the following experiment, for the purpose of proving the manner in which the electric current, transmitted to the stomach by the eight pairs of nerves, acts in transforming alimentary matter into chyle. He took a piece of boiled meat, and having added some water, in which were dissolved salt and subcarbonate of soda, kept it at an equable degree of heat, triturating it until it was reduced to a pulpy mass, analogous to that which is formed by mastication. He then put this pulp into a bladder moistened with a solution of salt, and placed it in contact with a platina wire, another wire being plunged into the interior of the mass. As soon as these two wires were brought into contact with a Voltaic battery of eighteen to twenty plates of copper and zinc, decomposition commenced about the extremities of the wires. At the negative extremity, which was in the centre of the mass, white bubbles of hydrogen gas were perceived; the liquid did not contain any traces of albumen, and was found to be alkaline. Along the walls of the bladder, and especially about the positive end of the wire, there was formed a dense white coat, acid, and distended with bubbles of oxygen gas. The collected substance was flocculent, and coagulated if, after having been dissolved in water, it was exposed to heat.

French Hospital Reports.

HÔTEL DIEU.

Unusual Quantity of Fluid in the Spinal Canal.

THE patient in this case was an old man of 68, who had always enjoyed good health. On the 12th of June, after being intoxicated, according to his wont, he remained in a state of delirium, with difficulty of movement, for some days. When he was admitted into the Hôtel Dieu, the tongue was covered with a thick white coat; he moved his limbs more freely than at first; his intellects were not completely destroyed, but he answered questions with difficulty; the pulse was feeble; he died on the 19th, after remaining 24 hours in a comatose state. On opening the spinal chord, 12 ounces 7 drachms and a half of fluid were found in the cerebro-spinal canal, and the membranes, with which the liquid was in contact, were of a thick white colour, and infiltrated.

Acute Pleuro Pneumonia cured by the Use of the White Oxide of Antimony.

An artificer was seized, on the 20th of December, with rigors, cough, and pain in the side; on the following day the respiration was quickened, the expectoration sanguineous, and there were symptoms of acute fever. Bleeding to a considerable amount was practised on the third day, and was followed by momentary relief. The disease, however, returned, and the dyspnoea, cough, and all the other symptoms noticed in pneumonia, were present. As his state did not present any thing very dangerous, M. Trosseau contented himself for two days with the employment of demulcents. On the third day the symptoms became more violent, and the expectoration was stopped; the brain became affected, and he was delirious. The white oxide of antimony was now given in doses of a drachm, and on the succeeding day the patient was decidedly better: the dyspnoea was less intense; the pulse of 100 had fallen to 76; the expectoration was abundant, and the delirium had completely left him; the tongue was moist, and he neither had nausea, vomiting, or diarrhoea; the urine more copious than ordinary, and the skin moist. After a few days the farther continuance of any remedies became unnecessary.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Secondary Syphilis.

MARY CAEN was admitted under the care of Mr. Walker with symptoms of this affection. The eruption occupied the face, arms, and body, and slightly affected the throat.

Seven or eight months ago, she had a chancre with gonorrhoea, for the relief of which she took mercury, which affected her system, and the sore and discharge were got rid of in six weeks. She remained well for six or seven weeks, and was then attacked with nocturnal pains affecting the tibia and ulna, with eruption, &c.

R. Decoct. Sardæ comp. Oj.,

Tinct. Uction. ʒiv. Misce et quotidie sumend.

R. Ly. Calcis, ʒviii.,
Oxymellis oleaginis, ʒiv. Misce, fiat gargarisma, gutturi utend.

R. Pil. Hydrarg. gr.v., bis in die sumend.

She pursued this course of treatment during nearly two months when a few copper-coloured spots only remained on some parts of the skin, which, however, disappeared on pressure, and she was soon afterwards discharged cured.

Tumour of the Gum.

Jane Sweten, æt. 16, was admitted under the care of Mr. Walker, and gave the following history. About three years since, the gum belonging to one of the upper incisor teeth began to enlarge until it increased to the size of a small bean; it was then excised, and afterwards grew slowly again, until about twelve months since, when it was again removed. It appeared to have entirely gone away for some time, but fifteen weeks since it again commenced growing, and is at present of the size of a pea. It was again removed with a lancet and some lunar caustic applied to the surface; there was some tendency to bleed, which was restrained by the application of some blue lint.

She had had amenorrhoea for fifteen weeks; her general health is otherwise very good.

R. Mistur. Camphor.
Decoct. Aloes comp. ʒʒ ʒvj.,
Sp. Ammon. Aromat. ʒss. Misce, fiat haustus ter in die sumend.

In a month's time, her general health had greatly improved; there was no return of swelling of the gum, and she was discharged cured.

Tubercular Disease of the Chin.

Ann Webb, æt. 13; six years since she had a gathering under the chin, which, after being poulticed, burst; it soon healed, and the cicatrix, which is slightly raised above the surrounding skin, and is sometimes more red than at others, has remained ever since about the

same size. About three years ago, another spot appeared on the chin, which appeared like a small pimple, but has since spread to the size of a bean.

She complains of having sick headaches; has not yet menstruated; appetite, &c. good, though she does not appear to be of strong constitution.

R. Hydrarg. submur., gr. iij.,
Pulvis Jalape comp. gr. xii. Cras
mane sumend.

July 16th.—R. Pulvis Rhei, gr. iij.,
Hydrarg. c. Creta, gr. vj.
Pulvis Zingib. gr. ij. Misce,

sumendus.

30th.—Unguent. Zinci parti affect. faciei
applicand.

Aug. 6th.—Sumat Vin. Ferri, 3i., ter die e
cyatho aquæ.

16th.—Unguent. Hydrarg. præcip. alb.;
parti affect. faciei applicand.

This last remedy was changed after a certain time to the following,

R. Unguent. Hydrarg. Nit. oxyd. 3i.,
Cerati Calaminæ, 3ss. Misce, fiat un-
guent, parti affect. applicand.

Sept. 27th.—The disease appeared at first to be improving under the use of these remedies; but their good effects after a time failed, and the following lotion was used.

R. Argent. Nitrat. gr. ij.,
Aque fontan., 3i. Misce, parti affect.
applicand.

This application was tried, and after a time the elevation of the tumour above the surrounding integuments was much less, and its vascularity was diminished, and in time it perfectly healed, and she was discharged quite well.

Ulceration of the Inter-Vertebral Substances.

A female patient was transferred from the care of Dr Seymour to Mr. Brodie, owing to a weakness in her spine and tottering in her walk, of which she had complained for some short time. Mr. Brodie, on examining her back, found that she complained of pain principally in the lumbar region of the spine, and that, a little above the seat of pain, there was a projection of the spinous process of one of the dorsal vertebræ. The history she gave of her case was, that she had felt pain and weakness in the back for seven months past, previous to which period she had been attacked with fever, cough, pain in the chest, &c. Mr. Brodie remarked, that this case was one of affection of the spine, and that it was a very common thing for pain to be felt by the patient below the actual seat of the disease. The affection in this case was not of the bones of the vertebræ themselves, but of the inter-vertebral cartilage between them, part of which, by being ulcerated, caused the body of the dorsal vertebræ above to tilt forwards, and the long spinous process to project backwards.

This case was not one of a scrofulous nature; first, because of the patient's age (between thirty and forty), which was beyond that period at which scrofulous affections show themselves; and, secondly, from the aspect of the patient's countenance, which was certainly not scrofulous. Mr. Brodie hinted to Dr. Seymour, that he should employ caustic issues and put on the patient a pair of stays.

Lithotomy.—Mr. Weiss's New Instrument.

I operated for lithotomy on a patient a few days since; the case was this. A gentleman came to me some time since for my advice; I found that he had some small calculi in the bladder, with inflammation and irritation of its coats, and a discharge of thick ropy mucus; he could not retain his water, which on being evacuated gave him intolerable pain. I really did not like the appearance of the case at first; it was not fit for Baron Heurteloup's operation, as the bladder would hold no water. I therefore commenced by injecting a weak solution of nitric acid into the bladder, in the proportion of one drop to one ounce, a remedy which I have found very useful in such cases. After using this for a time, I found the patient so far improved, that he was enabled to retain his water for a longer period of time, and I introduced a sound, and again detected the presence of urinary calculi. These had been originally formed by calcareous and earthy matters being deposited in the bladder, which had irritated its coats, and caused the secretion of ropy mucus, which in its turn had facilitated the further deposition of lithic matter, and thus the presence of these calculi was continued. It now, however, became necessary to destroy them; and, for this purpose, I employed an instrument manufactured by Mr. Weiss, of the Strand, and which I consider a very excellent and ingenious one,—it is formed on the same principle as Baron Heurteloup's; but, instead of a hammer, it breaks the calculi down by the force of a screw. It answers very well for soft stones, which they were in the case I allude to; and I suppose it would do the same for hard ones, for its power is very great. Mr. Brodie here referred to another case, somewhat similar to the preceding one, but in which the small calculi had been glued together, forming one large one. With reference to Baron Heurteloup's instrument, Mr. Brodie remarked, that it was a most excellent one, and the most perfect of the kind ever invented; but that, though he had seen many recover very well from the operation, with it he had also known many very nearly die from it; that, although from the bladder being filled with water, much injury to its coats from the broken fragments of calculi striking it was materially prevented, yet that sometimes great irritation and inflammation of the coats of the bladder followed. Mr. Brodie added, that he thought the use of the screw in an instrument preferable to that of a hammer, the former breaking the stone into

fragments quile as certainly, and with less violence than the latter. A pupil who, was present said, that in Baron Heurteloup's instrument the branches consisted of pieces of steel joined and riveted together, and not of one piece of metal, whereas Mr. Weiss manufactured and cut his out of one piece of finely tempered steel.

Use of Mercury in Syphilis combined with Scrofula.

There is a man at present in Winchester Ward, under the care of Mr. Brodie for secondary symptoms of syphilis, with eruption of rupiae on the skin, &c.; combined with this also he had enlarged scrofulous glands in the neck; yet, notwithstanding this, he has derived much benefit from taking the oxymercurate of mercury, and calomel, and opium. The swelling of the glands has abated, and his general aspect much improved. With reference to this case Mr. Brodie remarked, that it was commonly said that mercury was a bad thing to give in scrofulous cases. The fact was, that in this case the mercury had done the man a great deal of good,—the scrofula had lain dormant in the system, and the mercury had acted as a stimulant, and thrown the disease out. The man is evidently much better. On his first admission here he took the oxymercurate of mercury, which was afterwards changed for the calomel and opium; and you see how much he has improved under it.

APOTHECARIES' HALL.

LITERARY INTELLIGENCE.

MEDICA SACRA, or Short Expositions of the more important Diseases mentioned in the Sacred Writings. By THOMAS SHAPTER, M.D.

BOOKS.

AN Introduction to the Study of Human Anatomy. By JAMES PAXTON, M.R.C.S., &c., &c. With numerous Engravings. In 2 vols. Vol. II. London: 1834. Sherwood and Co. This is a most useful work for anatomical students, and, indeed, for all medical practitioners who wish to keep up their knowledge of anatomy. It is executed in the best manner. It is concise yet comprehensive, and every organ is illustrated with the greatest accuracy.

An Examination into the Causes of the Declining Reputation of the Medical Faculty of the University of Edinburgh, and the Origin of another class of Medical Professors, commonly called "Private Lecturers;" with some Remarks on the History of the University of Edinburgh. 8vo. pp. 58. Edinburgh: 1834. BARNES.

CORRESPONDENTS.

Scotus.—We shall be happy to receive the clinical reports: The other communication cannot be inserted. It refers to a period long passed.

Dr. Graves's communication shall be duly attended to.

Dr. O'Beirne's rejoinder to Mr. Salmon in our next.

E. C. W.—The article has been inserted.

A Medical Student.—It is impossible to know what changes may be made in the regulations of the Royal College of Surgeons.

Medicus.—The new by-laws of the College of Physicians are the most Jesuitical imaginable. The election of Fellows from among the Licentiates will be confined to Oxford, Cambridge, or Dublin graduates. The present Licentiates remain in *statu quo*, there may be one or two of them elected for the first year or two, but these will be physicians, who had a right to the Fellowship ten or twenty years ago. The Licentiates, as a body, must not relax in the cause of reform.

A Liverpool Correspondent.—The report of the reform meeting reached us last week after our number was at press; and, as a general meeting is called, we request our friends to forward us an account of the proceedings as soon as possible. The profession of every large town in the United Kingdom should follow the noble example of our Liverpool brethren, and petition both Houses of Parliament as early as possible, and oppose the grant of a Royal commission.

Dr. Slade's communication is under consideration. We feel obliged for his exertions in Devonshire.

An Anonymous Reviewer.—We never insert anonymous reviews or articles, unless when the writer communicates his name to us in confidence.

Several communications are under consideration.

Dr. Ryan has removed his residence to No. 4, Great Queen-street, St. James's Park, Westminster.

Errata.—In our report of the Westminster Medical Society, an inaccuracy occurred in the observations of Dr. Jewel: for "frequent contraction of the vagina," read "occasional contraction, which yielded during a subsequent parturition without any artificial aid."

ALL Communications and Books for Review to be forwarded (free of expense) to the Publisher, 356, Strand, near King's College.
